

DC Converter Equations Revisited

Normally the rectifier and inverter equations are written in terms of the *firing angles* α and γ .

Rectifier Equations	Inverter Equations
$V_{dcr} = \frac{3\sqrt{2}N}{\pi} \left[\frac{D_{base}}{Tap} \right] V_{ac} \cos(\alpha) - N \left[\frac{3X_c}{\pi} + 2R_c \right] I_{dc}$ $E_{ac} = \left[\frac{D_{base}}{Tap} \right] V_{ac}$ $\mu = \cos^{-1} \left[\cos \alpha - \frac{\sqrt{2}I_{dc}X_c}{E_{ac}} \right] - \alpha$	$V_{dci} = \frac{3\sqrt{2}N}{\pi} \left[\frac{D_{base}}{Tap} \right] V_{ac} \cos(\gamma) + N \left[-\frac{3X_c}{\pi} + 2R_c \right] I_{dc}$ $E_{ac} = \left[\frac{D_{base}}{Tap} \right] V_{ac}$ $\mu = \cos^{-1} \left[\cos \gamma - \frac{\sqrt{2}I_{dc}X_c}{E_{ac}} \right] - \gamma$

For transient stability purposes it is more convenient to write the inverter equations in terms of β . β is related to γ by $\beta = \mu + \gamma$. During the simulation we will need to flip back and forth between β and γ , thus express β as a function of γ and vice versa.

$$\beta = \cos^{-1} \left[\cos \gamma - \frac{\sqrt{2}I_{dc}X_c}{E_{ac}} \right] \quad \text{and} \quad \gamma = \cos^{-1} \left[\cos \beta + \frac{\sqrt{2}I_{dc}X_c}{E_{ac}} \right].$$

Now using the relationship $\cos \gamma = \cos \beta + \frac{\sqrt{2}I_{dc}X_c}{E_{ac}}$, rewrite the DC voltage equation for the inverter in terms of β .

$$V_{dci} = \frac{3\sqrt{2}N}{\pi} E_{ac} \left[\cos \beta + \frac{\sqrt{2}I_{dc}X_c}{E_{ac}} \right] + N \left[-\frac{3X_c}{\pi} + 2R_c \right] I_{dc}$$

$$V_{dci} = \frac{3\sqrt{2}N}{\pi} E_{ac} \cos \beta + N \left[\frac{6X_c}{\pi} I_{dc} \right] + N \left[-\frac{3X_c}{\pi} + 2R_c \right] I_{dc}$$

$$V_{dci} = \frac{3\sqrt{2}N}{\pi} E_{ac} \cos \beta + N \left[\frac{3X_c}{\pi} + 2R_c \right] I_{dc}$$

Using these equations, model the converter in the DC network equations as follows, with the extra constraint that the currents can NOT be negative.

Multi-Terminal DC Network DC Network Equations

$$R_{C1} = N_{C1} \left[\frac{3X_{CC1}}{\pi} + 2R_{CC1} \right]$$

$$R_{C3} = N_{C3} \left[\frac{3X_{CC3}}{\pi} + 2R_{CC3} \right]$$

$$E_{C1} = \frac{3\sqrt{2}N}{\pi} \left[\frac{D_{base}}{Tap} \right] V_{acC1} \cos(\alpha_{C1})$$

$$E_{C3} = \frac{3\sqrt{2}N}{\pi} \left[\frac{D_{base}}{Tap} \right] V_{acC3} \cos(\alpha_{C3})$$

Following are AC per unit voltages from the network equations.

$$V_{acS}, V_{acC3}, V_{acC1}$$

Following are outputs of the various dynamic DC converter models.

$$\cos(\beta_S), \cos(\alpha_{C1}), \cos(\alpha_{C1})$$

Note: For coding purposes it is easier to flip the direction of the current at the inverter and then just require that it be negative instead of positive

$$R_S = N_S \left[\frac{3X_{CS}}{\pi} + 2R_{CS} \right]$$

$$E_S = \frac{3\sqrt{2}N}{\pi} \left[\frac{DC_{base}}{Tap} \right] V_{acS} \cos(\beta_S)$$

Implementation of the numerical solution of the PDCI

In the normal network boundary equations and in Simulator's power flow engine, the DC converter control is assumed to be instantaneous. We assume that firing angle move instantaneously to bring DC currents instantaneously to a new operating point. For the PDCI we will be removing these assumptions completely and modeling the dynamics of the firing angle control. It is convenient for numerical reasons to make the control output of the DC converter equal to either $\cos(\alpha)$ and $\cos(\beta)$ depending on whether the converter is acting as a rectifier or inverter. Here we will describe how this changes the numerical simulation of the multi-terminal DC line.

Inside the transient stability engine in Simulator, an explicit integration method is used. Thus the general process of solving the equations is to use a numerical integration time step to update all dynamic state variables and then another step to update all the algebraic variables such as the AC system voltage and angle (network boundary equations). The MTDC simulation is added into this framework as follows.

During each time-step of the numerical simulation of the multi-terminal DC Line, the following steps are taken

1. Using the standard routines within Simulator to calculate the new states for the dynamic models MTDC_PDCI, CONV_CELILO_E, CONV_CELILO_N, and CONV_SYLMAR. This is done along with all the other thousands of dynamic models.
--> Updated Variables are $\cos(\alpha)$ or $\cos(\beta)$ terms for the DC converters
2. Before solving all the other algebraic equations using the AC network boundary equations, take the new $\cos(\alpha)$ and $\cos(\beta)$ terms and use them to model a step change in the DC voltages seen by the DC network equations. Use numerical integration to simulate the change in DC voltages and DC currents on the transmission lines for this time-step. Note that this is the only place in the numerical routines where the DC system currents in the system change.
--> Updated Variables are the DC voltages and DC Currents
3. Finally, when the normal AC network boundary equations are being solved we must modify how the DC network equations are handled. Without the dynamic model for the MTDC line modeled, we assume that the DC currents respond instantaneously to a change in the DC voltages by an instantaneous change in the converter firing angles. Because the PDCI is modeling the actual dynamics of the DC converter firing angle change, we must assume that the firing angles remain constant during the network boundary equation solution instead. In addition, the PTDC is a very long transmission line and thus has a substantial inductance, therefore the current cannot change instantaneously either and must be assumed constant during the network boundary equation solution. This means that in order to solve the DC network equations we must allow the voltages in the DC network to change but since we're not allowing the currents to change, then this means all voltage changes from resistances must be zero. This means that the new voltage variations must be coming from the inductor $L \cdot dI/dt$ terms. We will show this below.
--> Updated Variables are DC voltages

Numerical Integration to model the change in DC currents and DC voltages after a change in the $\cos(\alpha)$ and $\cos(\beta)$ terms

DC Converter equations are as follows, where R and E were described earlier. The unknown variable associated with this equation is the DC current. Note that it's possible for this to result in a current that is impossible (negative current injected into DC network for a rectifier or positive injection for an inverter). In that case we use a different equation which sets the current to zero.

$$RI + V_t = E \quad \text{or} \quad I = 0$$

DC transmission line equations are as follows. The unknown variable associate with this equation is the DC line current.

Use the trapezoidal rule to write the $dI/dt(n)$ term

$$V_k(n) - V_m(n) - RI(n) = \frac{2L}{h}I(n) - \left[\frac{2L}{h}I(n-1) + L \frac{dI}{dt}(n-1) \right]$$

Use the standard relationship above to write the $LdI/dt(n-1)$ term

$$V_k(n) - V_m(n) - RI(n) = \frac{2L}{h}I(n) - \left[\frac{2L}{h}I(n-1) \right] - [V_k(n-1) - V_m(n-1) - RI(n-1)]$$

Finally, group the terms that are a function of values at time (n) on the left and time $(n-1)$ on the right

$$V_k(n) - V_m(n) + \left(-R - \frac{2L}{h} \right) I(n) = \left(+R - \frac{2L}{h} \right) I(n-1) - V_k(n-1) + V_m(n-1)$$

DC Bus equation is just Kirchhoff's Current Law (KCL). The unknown variable associated with the equation is the DC bus voltage.

$$I_a + I_b + I_c + \dots = 0$$

Remember the trapezoidal integration rule:

$$\frac{dx}{dt}(n) + \frac{dx}{dt}(n-1) = \frac{x(n) - x(n-1)}{h}$$

which gives

$$\frac{dx}{dt}(n) = \frac{2}{h}x(n) - \left[\frac{2}{h}x(n-1) + \frac{dx}{dt}(n-1) \right]$$

Where n = the present integer time step

h = the duration of the time step

$x(n)$ = value at present time

$x(n-1)$ = value at previous time step

Using the PDCI as an example, the following matrix equations are created.

	Ic1	Ic3	Is	Ic	Ia	Ib	Id	v3	v4	v7	v8	v9	X	B
Celilo1	Rc1									1			Ic1 _(n)	Ec1
Celilo3		Rc3									1		Ic3 _(n)	Ec2
Sylmar1			Rs									1	Is _(n)	Es
LineC				$(-Rc-2Lc/h)$				1	-1				Ic _(n)	$(+Rc-2Lc/h)*Ic_{(n-1)}$ $- v3_{(n-1)} + v4_{(n-1)}$
LineA					$(-Ra-2La/h)$			-1		1			Ia _(n)	$(+Ra-2La/h)*Ia_{(n-1)}$ $- v7_{(n-1)} + v3_{(n-1)}$
LineB						$(-Rb-2Lb/h)$		-1			1		Ib _(n)	$(+Rb-2Lb/h)*Ib_{(n-1)}$ $- v8_{(n-1)} + v3_{(n-1)}$
LineD							$(-Rd-2Ld/h)$		-1			1	Id _(n)	$(+Rd-2Ld/h)*Id_{(n-1)}$ $- v9_{(n-1)} + v4_{(n-1)}$
KCL3				-1	1	1							v3 _(n)	0
KCL4				1			1						v4 _(n)	0
KCL7	1				-1								v7 _(n)	0
KCL8		1				-1							v8 _(n)	0
KCL9			1				-1						v9 _(n)	0

Simulator solves this set of equations by splitting the actual integration time-step used in the standard numerical integration and dividing it by 10. We set the h variable above to the time step divided by 10 then iterate this set of equations 10 times. When solving these equations, we initially assume that none of the currents end up the wrong sign. Then after each sub time step we check if the converter currents end up as the wrong sign. If converter currents have the wrong sign, we automatically change the equation for the offending converter to force that converter current to zero and redo this sub time step. We assume the converter current remains zero during the remainder of this time step and only allow it to back-off this limit during the following time step. I believe the current would never bounce around during a time step anyway, because this is fundamentally only a set of RL circuits so you will only get a first-order RL circuit exponential decay response toward the new steady state.

As an example, if the current at Celilo1 ended up the wrong sign, then its matrix equation would be rewritten as

Celilo1	1									0			Ic1 _(n)	0
---------	---	--	--	--	--	--	--	--	--	---	--	--	--------------------	---

Solution of the algebraic change in DC voltages during the AC network boundary equation solution

DC Converter equations are as follows, where R and E were described earlier. Also note that the DC current is assumed constant so it is moved to the right side as a known quantity. The unknown variable associated with this equation is the voltage at the terminal.

$$V_t = E - RI$$

DC transmission line equations are as follows. The unknown variable associated with equation is the *derivative* of the DC current. The DC current is assumed constant during the AC network boundary equation solution.

$$V_k - V_m - L \frac{dI}{dt} = RI$$

DC Bus equation is just Kirchhoff's Current Law (KCL), but for the derivatives of the currents instead of the actual currents. The unknown variable associated with the equation is DC bus voltage. Also note that we only add an equation for DC buses which are not connected to a DC converter terminal.

$$\frac{dI_a}{dt} + \frac{dI_b}{dt} + \frac{dI_c}{dt} + \dots = 0$$

Using the PDCI as an example, the following matrix equations are created

LineC	-Lc						1	-1	=	dIc/dt	Ic*Rc
LineA		-La			1		-1			dIa/dt	Ia*Ra
LineB			-Lb			1	-1			dIb/dt	Ib*Rb
LineD				-Ld			1	-1		dId/dt	Id*Rd
Celilo1					1					v7	Ec1-Rc1*Ic1
Celilo3						1				v8	Ec3-Rc3*Ic3
Sylmar1							1			v9	Es-Rs*Is
KCL3	-1	1	1					0		v3	0
KCL4	1			1				0		v4	0

General Overview of Multi-Terminal DC Line Model for the Pacific DC Intertie

Simulator has a multi-terminal DC (MTDC) record which represents the grouping of the dc converters, dc buses and dc lines for a single pole of a MTDC transmission line. The Pacific DC Intertie (PDCI) is represented by two of these records: one for each pole of the PDCI. For the PDCI, each MTDC record contains three DC converters with two at Celilo (North end) and one at Sylmar (South end). In Simulator these DC converters are also represented by unique objects.

The transient stability model of the PDCI works by assigning a dynamic model to each of the two MTDC records, and also assigning a dynamic model to each of the DC converter objects. To model this, there are 4 dynamic models

MTDC_PDCI	Assigned to the MTDC record.
CONV_CELILO_E	Assigned to the Celilo DC converter at the 230 kV bus at Celilo (North). Note: "E" stands for "existing"
CONV_CELILO_N	Assigned to the Celilo DC converter at the 500 kV bus at Celilo (North). Note: "N" stands for "new"
CONV_SYLMAR	Assigned to the DC converter at Sylmar (South)

The flow of signals is depicted in the following image.

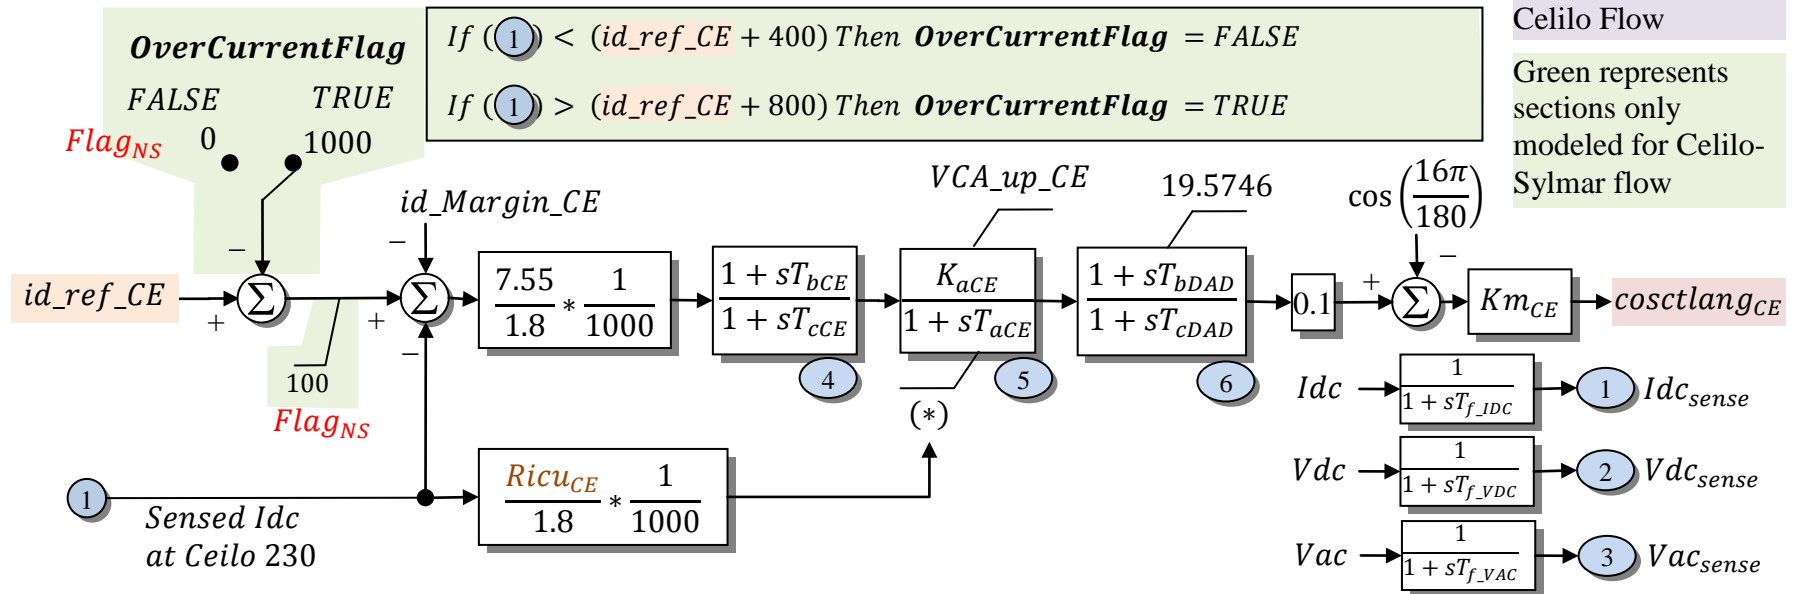

The function of the converts is generally described as follows.

MTDC_PDCI	Assigned to the MTDC record. Model will coordinate the allocation of current order reference signals sent to the three DC converters that it manages. Model may also pass on various flags such a <i>VacLow</i> . Model receives signals of sensed AC and DC voltage and DC current from the converters also. The two MTDC_PDCI models will act independently of one another, except that each record passes a measurement of the DC voltage at the rectifier end of each pole to the other pole.
CONV_CELILO_E	Assigned to the "existing" Celilo DC converter at the 230 kV bus at Celilo (North). Converter initializes its Isched and Psched values to those from the initial network boundary equation solution. Model will take as an input one signals from MTDC_PDCI: the current order reference signal (<i>Id_ref_CE</i>).
CONV_CELILO_N	Assigned to the "new" Celilo DC converter at the 500 kV bus at Celilo (North). Converter initializes its Isched and Psched values to those from the initial network boundary equation solution. Model will take as an input two signals from MTDC_PDCI: the current order reference signal (<i>Id_ref_CN</i>) and the flag <i>VacLow</i> .
CONV_SYLMAR	Assigned to the DC converter at Sylmar (South). Converter initializes its Isched and Psched values to those from the initial network boundary equation solution. Model will take as an input one signalsfrom MTDC_PDCI: the current order reference signal (<i>Id_ref_S</i>).

In addition the implementation of these four models will be automatically modify based on the initial flow in the initial system flow direction (depending whether the flow is from Celilo to Sylmar or Sylmar to Celilo). These modifications reflect the differences in how each converter behaves when acting as a rectifier or inverter. In the following block diagrams portions of the model which are only used for a flow from Celilo to Sylmar (North to South) are highlighted in green, while portion only used for a flow from Sylmar to Celilo (North to South) are highlighted in purple. Differences also have a red notation of *Flag_{NS}* added to denote highlighting. Values which are passed between models are highlighted in orange. Outputs of the control angle for DC converters are highlighted in pink.

CONV_CELILO_E **Celilo 230 kV Converter Controls (Celilo Existing Controls)**

Purple represent sections only modeled for Sylmar-Celilo Flow

Green represents sections only modeled for Celilo-Sylmar flow

CONV_CELILO_E parameters are all hard-coded based on whether the initial flow direction of the PDCI. The parameters and the initialization are different for Celilo to Sylmar (North to South) or Sylmar to Celilo (South to North) flow. The following table shows the differences

Parameter	Celilo-Sylmar (North to South)	Sylmar - Celilo (South to North)
T_{bCE}	0.0323	
T_{cCE}	0.0323	
K_{aCE}	330	82.5
T_{aCE}	8.1500	
VCA_up_CE	20	8.5
T_{bDAD}	0	1/240
T_{cDAD}	1/60	
Km_{CE}	1	-1
id_margin_CE	0	180

Initialization Reference Values	Celilo-Sylmar (North to South)	Sylmar - Celilo (South to North)
$Ricu_{CE}$	2.2	Initialize so State 5 is at its lower limit $Ricu_{CE} = \frac{(4) * 1.8 * 1000}{(1)}$
Parameter	Celilo-Sylmar (North to South)	Sylmar - Celilo (South to North)
$IdRefLim_{CE}$	2160	
T_{f_IDC}	0.004	0.0084
T_{f_VDC}	0.004	0.0084
T_{f_VAC}	0.0333	

CONV_CELILO_N parameters are all hard-coded based on whether the initial flow direction of the PDCI. The parameters and the initialization are different for Celilo to Sylmar (North to South) or Sylmar to Celilo (South to North) flow. The following table shows the differences.

Parameter	Celilo-Sylmar (North to South)	Sylmar - Celilo (South to North)
id_Margin_CN	0	150
$IdRefLim_CN$	1650	
$idtrip_CN$	+110	-110

MTDC_PDCI

Current Order Allocation Calculations for Celilo and Sylmar

MTDC_PDCI (North to South Implementation) Measurements and Low Voltage Detection Logic

DC Voltage Measurement Freeze

If **VLowFlag** = TRUE then activate a timer **TimerVDCFreeze** and set timer to **Tdel_{friz}**. Continue to set this timer up to **Tdel_{friz}** as long as **VLowFlag** is TRUE. If **VLowFlag** become FALSE then start having the timer count down to zero. Once the **TimerVDCFreeze** reaches zero then make it inactive.

Whenever **TimerVDCFreeze** is inactive then

Set **VDCFreeze** = (2)

and pass (1) as the DC voltage to Current Order Allocation Calculation

Whenever **TimerVDCFreeze** is active then

Pass the variable **VDCFreeze** as the DC voltage to the Current Order Calculation

Pole Current Margin Compensator

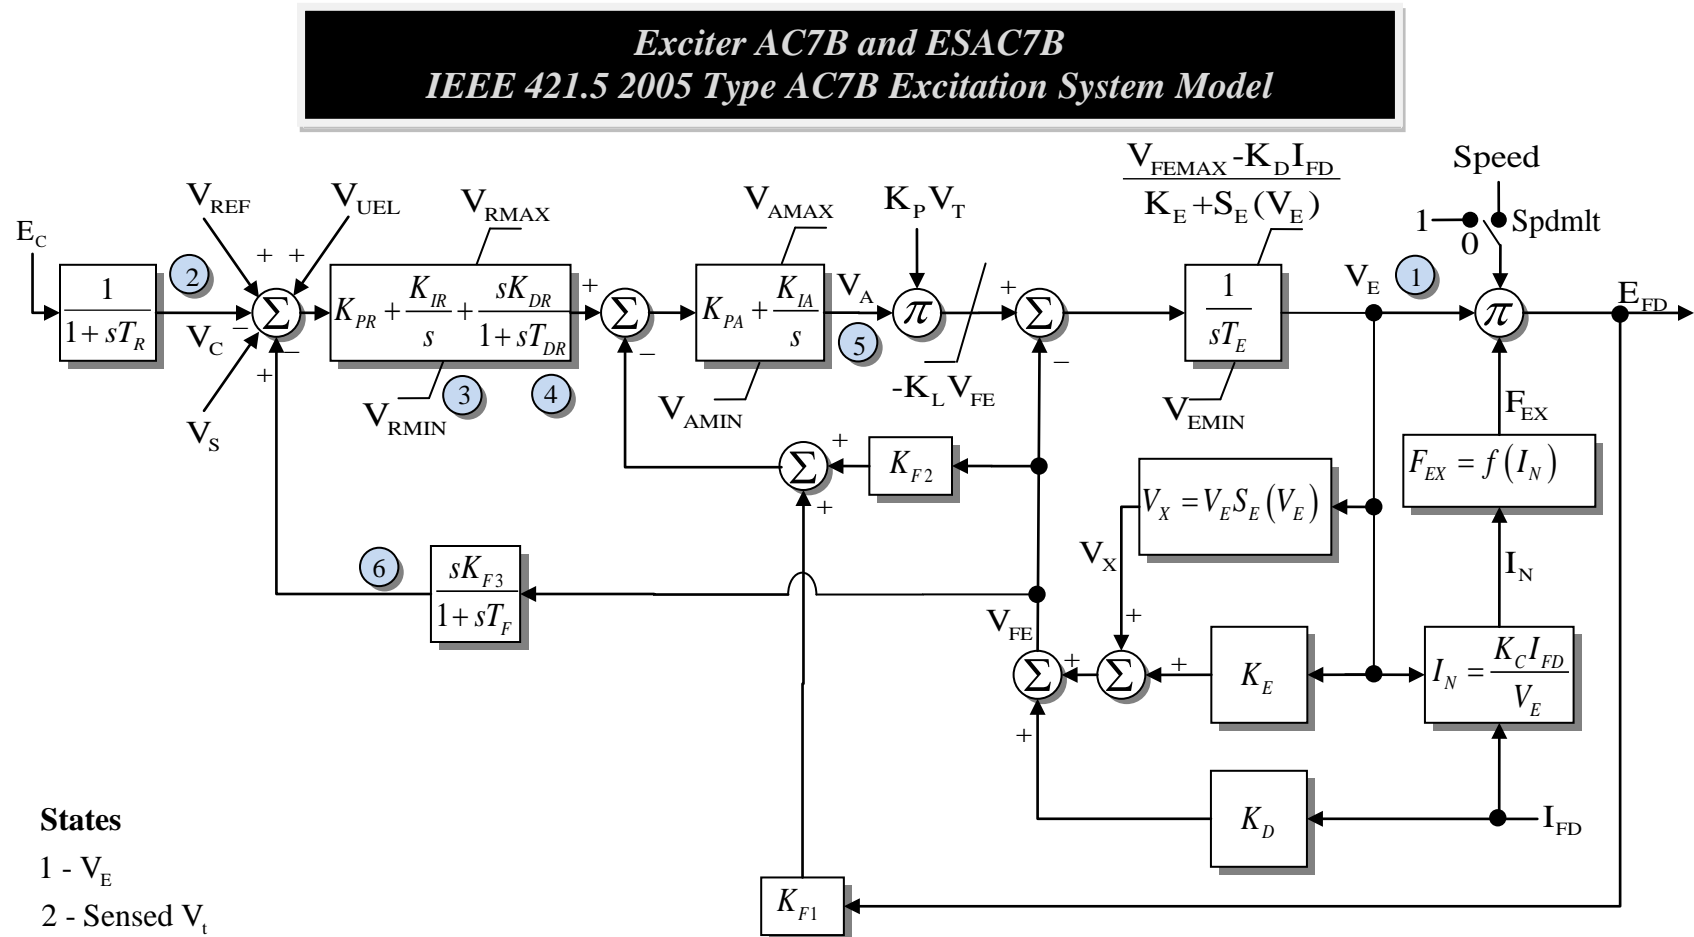

If **VLowFlag** = TRUE then activate a timer **TimerPCMC** and set timer to **Tpcmc_rst**. Continue to set this timer up to **Tpcmc_rst** as long as **VLowFlag** is TRUE. If **VLowFlag** become FALSE then start having the timer count down to zero. Once the **TimerPCMC** reaches zero then make it inactive.

MTDC_PDCI Parameters are all hard-coded based on whether the initial flow direction of the PDCI. The parameters and the initialization are different for Celilo to Sylmar (North to South) or Sylmar to Celilo (South to North) flow. The following table shows the differences

Parameter	Celilo-Sylmar (North to South)	Sylmar - Celilo (South to North)
T_{fpcmc_rst}	0.1	
T_{VDC_friz}	0.53	
$Tdel_{friz}$	0.44	
$VacRefVDCL$	228/230	n/a
$ACVdclmax$	3100	n/a
$ACVdclmin$	2400	n/a
$T_{vcacvdcol}$	0.5	n/a
$IdRefLim_{CE}$	Get from CONV_CELILO_E model	
$IdRefLim_{CN}$	Get from CONV_CELILO_N model	
$IdRefLim_S$	Get from CONV_SYLMAR model	
T_{v_bcoc}	0.05	
T_{pcmc}	0.5120	
T_{icmc}	n/a	0.2500
Id_margin_CE	Get from CONV_CELILO_E model	
$TIdc$	0.5 cycles	
$Tdelay$	2 cycles	

Initialization Reference Values	Celilo-Sylmar (North to South)	Sylmar - Celilo (South to North)
$pord_pole$	Initialize to Sum of Psched at two Celilo Converters	Initialize to Psched at the Sylmar Converter
K_c	Initialize based on the following equation $K_c = \frac{id_ref_CE}{id_ref_CE + id_ref_CN}$	
$VacLowSylmar$	FALSE	
$VacLowCelilo$	FALSE	
$VdcLow$	FALSE	
$VLowFlag$	FALSE	
$IdInitRef_c$	n/a	Initialize equal to State 14 to handle difference between id_ord_pole and id_ref_S
$IdInitRef_s$	Initialize equal to State 14 to handle difference between id_ord_pole and id_ref_CN + id_ref_CE	n/a

Exciter PLAYINEX

With the PLAYINEX model, specify the index (FIndex) of a specified PlayIn structure. That signal will then be played into the model as the field voltage during the simulation.

PlayIn	<input type="text" value="none"/>	<input type="button" value="Choose..."/>
FIndex	<input type="text" value="1"/>	<input type="button" value="↑"/> <input type="button" value="↓"/>

Exciter REEC_A

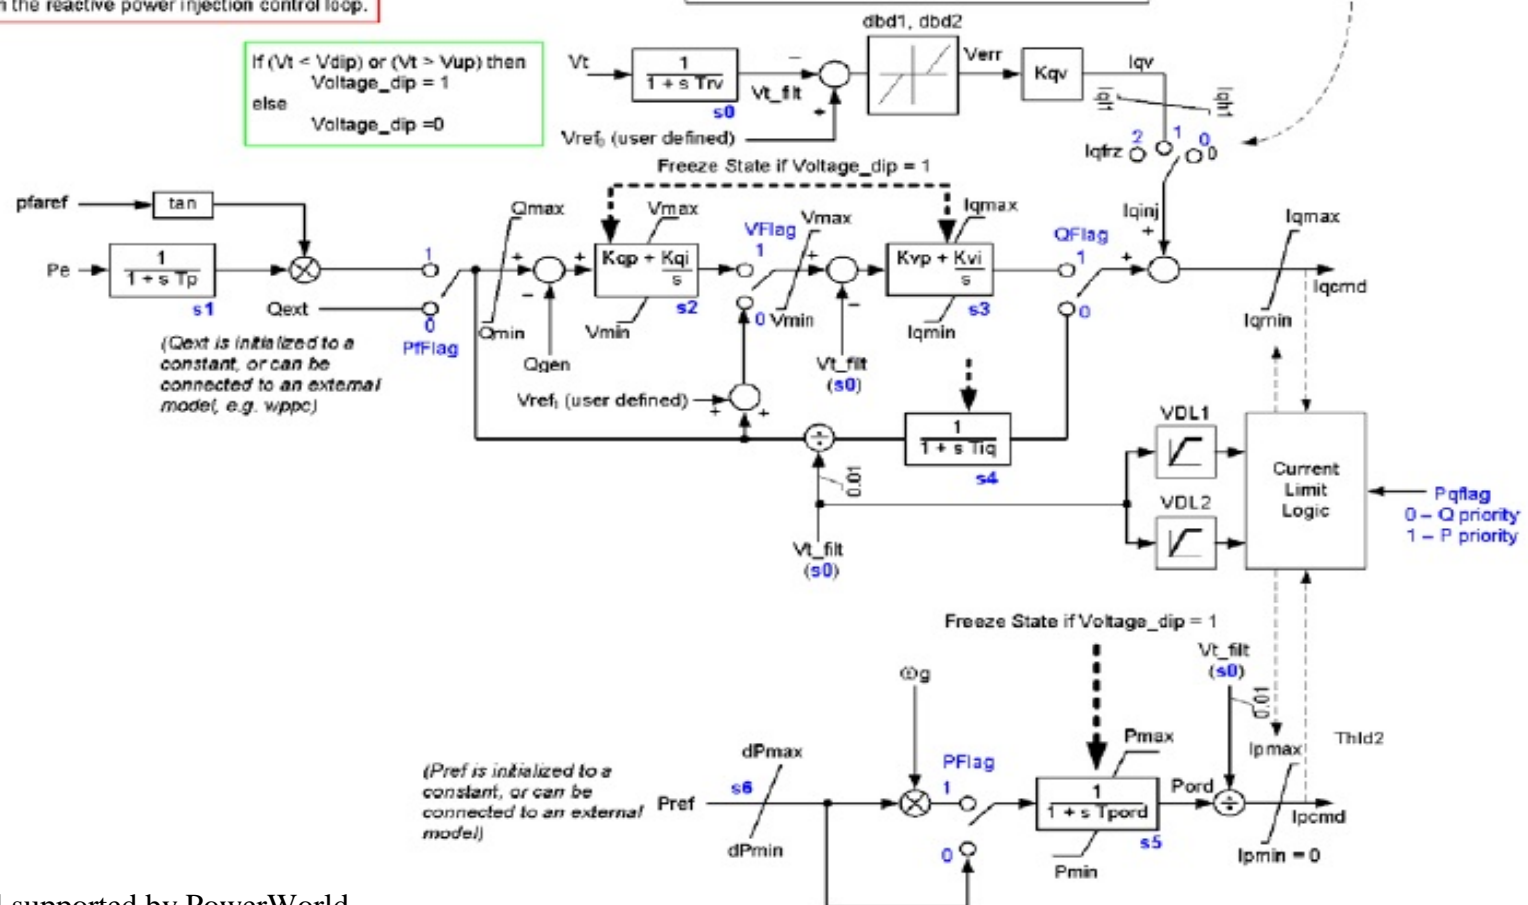

Renewable Energy Electrical Control Model REEC_A

Warning!!

Extreme care should be taken in coordinating the parameters dbd1, dbd2 and Vdip, Vup so as not to have an unintentional response from the reactive power injection control loop.

If $(V_t < V_{dip})$ or $(V_t > V_{up})$ then
Voltage_dip = 1
else
Voltage_dip = 0

State Transition = switch position
State 0 - If Voltage_dip = 0, normal operation ($I_{qinj} = 0$)
State 1 - If Voltage_dip = 1, I_{qinj} goes to position 1
State 2 - If $Thid > 0$, then after voltage_dip goes back to zero, set value to I_{qfrz} for $t = Thid$, after which go back to state 0.
- If $Thid < 0$, then after voltage_dip returns to zero stay in State 1 for $t = Thid$, after which go back to state 0.

IEEE1_GE is supported by PSLF. PowerWorld ignores the db2 term. All values are specified on the turbine rating which is a parameter in PowerWorld and PSLF. If the turbine rating is omitted or zero, then the generator MVABase is used. If there are two generators, then the SUM of the two MVABases is used.

IEEE1 is supported by PSSE. PSSE does not include the db2, db1, non-linear gain term, or turbine rating. For the IEEE1 model, if the turbine rating is omitted then the MVABase of only the high-pressure generator is used.

GV1, PGV1...GV6, PGV6 are the x,y coordinates of P_{GV} vs. GV block

Line Relays DISTR1

Three-Zone Distance Relay with Transfer Trip

Relays are assigned to a specific end of a branch. This end is specified by the column **Device Location** which can be set to either *From* or *To*. It is specified on the branch dialog by checking the box **Device is at From End of Line (otherwise at To End)**. The end specified by the **Device Location** is referred to as the "Relay End", while the other is referred to as the "Other End". When this relay's conditions are met, the entire branch is opened.

There are three zones for the relay which depend on the zone shape specified. The zone shapes are determined by the Impedance Type integer. 1 = mho Distance shapes, 2 = impedance distance, and 3 = reactance distance. In addition to these shapes, two blinders may be specified which block all zones. These are described on the next page.

Each zone has a time in cycles associated it. When the apparent impedance enters the zone, a timer is started. If the impedance stays inside the zone for the specified number of cycles, then the relay will send a trip signal to the breaker. The breaker will then trip after the *Self Trip Breaker Time* has elapsed. Three additional branches may also be specified as *Transfer Trip Branch 1, 2, and 3*. These branches use the *Transfer Trip breaker time* instead.

Optionally, after the branches are tripped, the branches may reclose after a specified number of cycles according to the *Self Trip Reclosure Time* or *Transfer Trip Reclosure time*. This reclosure will happen only once during the simulation.

Other field results include signals associated with a particular zone which have the following meanings.
 0 : not picked up (not in Zone)
 1 : Picked up, not timed out
 2 : Picked up, timeout complete

Other field results include signals associated with a breaker. For breaker signals, the values have the following meanings.
 0 : Trip not initiated
 1 : Trip initiated, CB timer running
 2 : Breaker has tripped

The following pseudo code describes how the inputs are used to determine series capacitor switching:

SeriesCap = Series capacitor to which this model is assigned

LineSectionsAreOpen = Any line section open for Extra Object 1 to 7

CapBlocked = ((Interface1 MW Flow < -50) OR (Interface1 MW Flow > 0)) AND LineSectionsAreOpen

If ((not CapBlocked) and (SeriesCap.Status = Bypassed))

 AND

 ((Monitored Bus Voltage < volt_low for td_low) OR (Monitored Bus Voltage < volt_high for td_high))

Then Begin

 SeriesCap.Status = Not Bypassed

End

Line Relays LOCTI

Time Inverse Over-Current Relay

Relays are assigned to a specific end of a branch. This end is specified by the column **Device Location** which can be set to either *From* or *To*. It is specified on the branch dialog by checking the box **Device is at From End of Line (otherwise at To End)**. The end specified by the **Device Location** is referred to as the "Relay End", while the other is referred to as the "Other End".

When this relay's conditions are met, the entire branch is opened.

Relay Operation

The TimeToClose varies according to the piecewise linear function of per unit current as shown to the right and as specified by the input values Threshold, m1..m5, and t1..t5. If m1 is greater than 1.0, then an additional point at the Threshold current of 1 hour (3,600 seconds) is added to the curve.

The time at which the relay will close is determined by integrating the following function. When the function equal 1.0 then the relay will close.

$$\theta = \int \left[\frac{1}{\text{TimeToClose}} \right] dt$$

Relay Resetting

When the current drops below the *Threshold* current, then the relay resets according to the parameter *TReset*. If *TReset* is zero, then the relay resets to $\theta = 0$ instantaneously. Otherwise there is a timed reset which occurs by integrating using the function

$$\theta = \int \left[1 - \left(\frac{I_{\text{Current}}}{\text{Threshold}} \right)^2 \right] \left[\frac{-1}{T_{\text{Reset}}} \right] dt$$

This function means that at zero current, it completely resets in *TReset* seconds.

Monitor Flag

If the monitor flag is 0, then the relay will create result events to indicate that lines would have tripped, but will not actually trip any lines. If monitor flag is not zero, then the relay will send a trip signal to the branch when $\theta \geq 1$ and the branch will trip after the *Breaker Time* seconds have elapsed.

Type: Active - OOSLEN ID=1 (From) ☒ Active

Line Relays OOSLEN

Out-of-step relay with 3 zones OOSLEN

Relays are assigned to a specific end of a branch. This end is specified by the column **Device Location** which can be set to either *From* or *To*. It is specified on the branch dialog by checking the box **Device is at From End of Line (otherwise at To End)**. The end specified by the **Device Location** is referred to as the "Relay End", while the other is referred to as the "Other End".

When this relay's conditions are met, only the Relay End of the branch is opened (determined by **Device Location**). However, the relay will determine if the line presently serves a radial system (i.e. the *Nfar* bus branch is already open). If a radial system is served, then all devices such as load or generation is also opened.

Multiple OOSLEN relays can be assigned to the same end of a branch. In order to distinguish between them there is an extra key field called Device ID which must be specified for the OOSLEN. When loading from an auxiliary file, if this field is omitted, Simulator assumes value of "1".

Other field results include signals associated with a particular zone which have the following meanings.

0 : not picked up (not in Zone)
1 : Picked up, not timed out
2 : Picked up, timeout complete

Other field results include signals associated with a breaker. For breach signals, the values have the following meanings.

0 : Trip not initiated
1 : Trip initiated, CB timer running
2 : Breaker has tripped

Line Relays TIOCR1

Time Inverse Over-Current Relay

Relays are assigned to a specific end of a branch. This end is specified by the column **Device Location** which can be set to either *From* or *To*. It is specified on the branch dialog by checking the box **Device is at From End of Line (otherwise at To End)**. The end specified by the **Device Location** is referred to as the "Relay End", while the other is referred to as the "Other End". When this relay's conditions are met, the entire branch is opened.

Type: Active - OOSLEN ID=1 (From) ☒ Active

Device ID: 1 ☒ Device is at From End of Line (otherwise at To End)

	From Number	To Number	Circuit	From Name_Nominal kV	To Name_Nominal kV	Device Location	Device ID	Type
1	4	1	1	Bus 4_230.00	Bus1_16.50	From	1	OOSLEN
2	4	1	1	Bus 4_230.00	Bus1_16.50	To	1	OOSLNQ
3	2	7	1	Bus 2_18.00	Bus 7_230.00	From		ZLIN1
4	5	4	1	Bus 5_230.00	Bus 4_230.00	To		ZLIN1

Relay Operation

The TimeToClose varies according to the piecewise linear function of per unit current as shown to the right and as specified by the input values Threshold, m1..m5, and t1..t5. If m1 is greater than 1.0, then an additional point at the Threshold current of 1 hour (3,600 seconds) is added to the curve.

The time at which the relay will close is determined by integrating the following function. When the function equal 1.0 then the relay will close.

$$\theta = \int \left[\frac{1}{\text{TimeToClose}} \right] dt$$

Relay Resetting

When the current drops below the *Threshold* current, then the relay resets according to the parameter *TReset*. If *TReset* is zero, then the relay resets to $\theta = 0$ instantaneously. Otherwise there is a timed reset which occurs by integrating using the function

$$\theta = \int \left[1 - \left(\frac{I_{\text{Current}}}{\text{Threshold}} \right)^2 \right] \left[\frac{-1}{T_{\text{Reset}}} \right] dt$$

This function means that at zero current, it completely resets in *TReset* seconds.

Monitor Flag

If the monitor flag is 0, then the relay will create result events to indicate that lines would have tripped, but will not actually trip any lines. If monitor flag is not zero, then the relay will send a trip signal to the branch when $\theta \geq 1$ and the branch will trip after the *Breaker Time* seconds have elapsed.

Transfer Trip

Trip signals for this relay may be sent to three different branches by pointing to branches for *Transfer Trip 1*, *Transfer Trip 2*, and *Transfer Trip 3*. In addition, a *Transfer Trip Load* record may also be pointed to with a corresponding parameter *Load Shed %* specifying what percentage of the load should be tripped.

Model Supported by PSSE

Line Relays TIOCRS

Time Inverse Over-Current Relay Standard

This relay is identical in all respects to the TIOCR1 relay, except for how the *TimeToClose* time-inverse overcurrent curve is specified. This includes the treatment of the Monitor Flag, Transfer Trip, and Reset functions. For TIOCRS, instead of using a piece-wise linear curve, a function as described in various world standards is used. To specify which standard to use, the parameter *CurveType* must be set to either 1, 2, or 3 which translates to the following standards.

1. IEEE C37.112-1996 standard
2. IEC 255-4 or British BS142
3. IAC Curves from GE

The *TimeToClose* functions are specified by the parameters T_{dm} , p , A , B , C , D , and E depending on the Curve Type. The three standards are shown below. (Note: The use of the reset time is identical for all standards and is the same as used in TIOCR1 and LOCTI).

IEEE C37.112-1996 Standard (*CurveType* = 1)

Using the parameters *Threshold*, T_{dm} , p , A , and B , the *TimeToClose* as a function of per unit current is calculated using the following equations

$$TimeToClose = T_{dm} \left(B + \frac{A}{\left(\frac{I_{current}}{Threshold} \right)^p - 1} \right)$$

IEC 255-4 or British BS142 Standard (*CurveType* = 2)

Using the parameters *Threshold*, T_{dm} , p , and A the *TimeToClose* as a function of per unit current is calculated using the following equations

$$TimeToClose = T_{dm} \left(\frac{A}{\left(\frac{I_{current}}{Threshold} \right)^p - 1} \right)$$

IAC GE Curves (*CurveType* = 3)

Using the parameters *Threshold*, T_{dm} , A , B , C , D , and E the *TimeToClose* as a function of per unit current is calculated using the following equations

$$TimeToClose = T_{dm} \left(A + \frac{B}{\left(\frac{I_{current}}{Threshold} - C \right)} + \frac{D}{\left(\frac{I_{current}}{Threshold} - C \right)^2} + \frac{E}{\left(\frac{I_{current}}{Threshold} - C \right)^3} \right)$$

Extra note: Any current higher than 30 times the threshold is simply treated as though it is equal to 30 times the threshold in these equations.

Line Relays TLIN1

Under-voltage or Under-frequency Relay Tripping Line Circuit Breaker(s) TLIN1

Relays are assigned to a specific end of a branch. This end is specified by the column **Device Location** which can be set to either *From* or *To*. It is specified on the branch dialog by checking the box **Device is at From End of Line (otherwise at To End)**. The end specified by the **Device Location** is referred to as the "Relay End", while the other is referred to as the "Other End".

When this relay's conditions are met, the tripping which occurs depends on the Flag parameter as follows

- 0 : Only the Relay End of the branch is opened (determined by **Device Location**).
- 1 : Both ends of the branch are opened and the far end branch is also opened.
- 2 : Only the Relay End of the branch is opened (determined by **Device Location**). However, the relay will determine if the line presently serves a radial system (i.e. the *Nfar* bus branch is already open). If a radial system is served, then all devices such as load or generation is also opened.

Model supported by PSLF

The value monitored by this relay is determined by the Input parameter.

0 : means frequency in Hz

1 : means per unit voltage

The bus at which this value is monitored is specified by signal bus (SBus). If a signal bus is not specified, then the Relay End bus will be used instead.

The relay condition is met if the monitored value falls below the pickup value (V1) at least the relay definite time settings (T1). When the relay is condition is met the trip will occur after the circuit breaker time delay (Tcb1)

An Other Field include a signal which have the following meanings.

0 : not picked up (not in Zone)

1 : Picked up, not timed out

2 : Picked up, timeout complete

3 : Circuit Breaker Trip Complete

Line Relays ZDCB

Distance Relay with Directional Comparison Blocking (ZDCB)

Relays are assigned to a specific end of a branch. This end is specified by the column **Device Location** which can be set to either *From* or *To*. It is specified on the branch dialog by checking the box **Device is at From End of Line (otherwise at To End)**. The end specified by the **Device Location** is referred to as the "Relay End", while the other is referred to as the "Other End".

For Zone 1, the region is the same for both ends of the branch and each end trip independently if their Zone 1 conditions are met.

For higher zone tripping to occur, then Zone 2 conditions must be met at one end while simultaneously the Zone 3 conditions at the *other* end are *not* met.

Type: Active - OOSLEN ID=1 (From) ☒ Active

Load Characteristic IEEL

Load Characteristic IEEL *Complex Load Model*

$$P = P_{load} \left(a_1 v^{n_1} + a_2 v^{n_2} + a_3 v^{n_3} \right) (1 + a_7 \Delta f)$$

$$Q = Q_{load} \left(a_4 v^{n_4} + a_5 v^{n_5} + a_6 v^{n_6} \right) (1 + a_8 \Delta f)$$

Load Characteristic LD1PAC

Load Characteristic Model LD1PAC

Pul	Fraction of constant power load
TV	Voltage input time in sec.
Tf	Frequency input time constant in sec.
CompPF	Compressor Power Factor
Vstall	Compressor Stalling Voltage in p.u.
Rstall	Compressor Stall resistance in p.u.
Xstall	Compressor Stall impedance in p.u.
Tstall	Compressor Stall delay time in sec.
LFadj	Vstall adjustment proportional to loading factor
KP1 to KP2	Real power coefficient for running states, p.u.P/p.u.V
NP1 to NP2	Real power exponent for running states
KQ1 to KQ2	Reactive power coefficient for running states, p.u.Q/p.u.
NQ1 to NQ2	Reactive power exponent for running states
Vbrk	Compressor motor breakdown voltage in p.u
Frst	Restarting motor fraction
Vrst	Restart motor voltage in p.u.
Trst	Restarting time delay in sec.
CmpKpf	Real power frequency sensitivity, p.u.P/p.u.
CmpKqf	Reactive power frequency sensitivity, p.u.Q/p.u.

Vc1off	Voltage 1 contactor disconnect load in p.u.
Vc2off	Voltage 2 contactor disconnect load in p.u.
Vc1on	Voltage 1 contactor re-connect load in p.u.
Vc2on	Voltage 2 contactor re-connect load in p.u.
Tth	Compressor heating time constant in sec.
Th1t	Compressor motors begin tripping
Th2t	Compressor motors finished tripping
fuvr	Fraction of compressor motors with undervoltage relays
uvtr1 to uvtr2	Undervoltage pickup level in p.u.
ttr1 to ttr2	Undervoltage definite time in sec.

Model supported by PSLF

Load Characteristic LDFR

Load Characteristic LDFR Complex Load Model

$$P = P_o \left(\frac{\omega}{\omega_o} \right)^m$$

$$Q = Q_o \left(\frac{\omega}{\omega_o} \right)^n$$

$$I_p = I_{po} \left(\frac{\omega}{\omega_o} \right)^r$$

$$I_q = I_{qo} \left(\frac{\omega}{\omega_o} \right)^s$$

Load Characteristic LDRANDOM

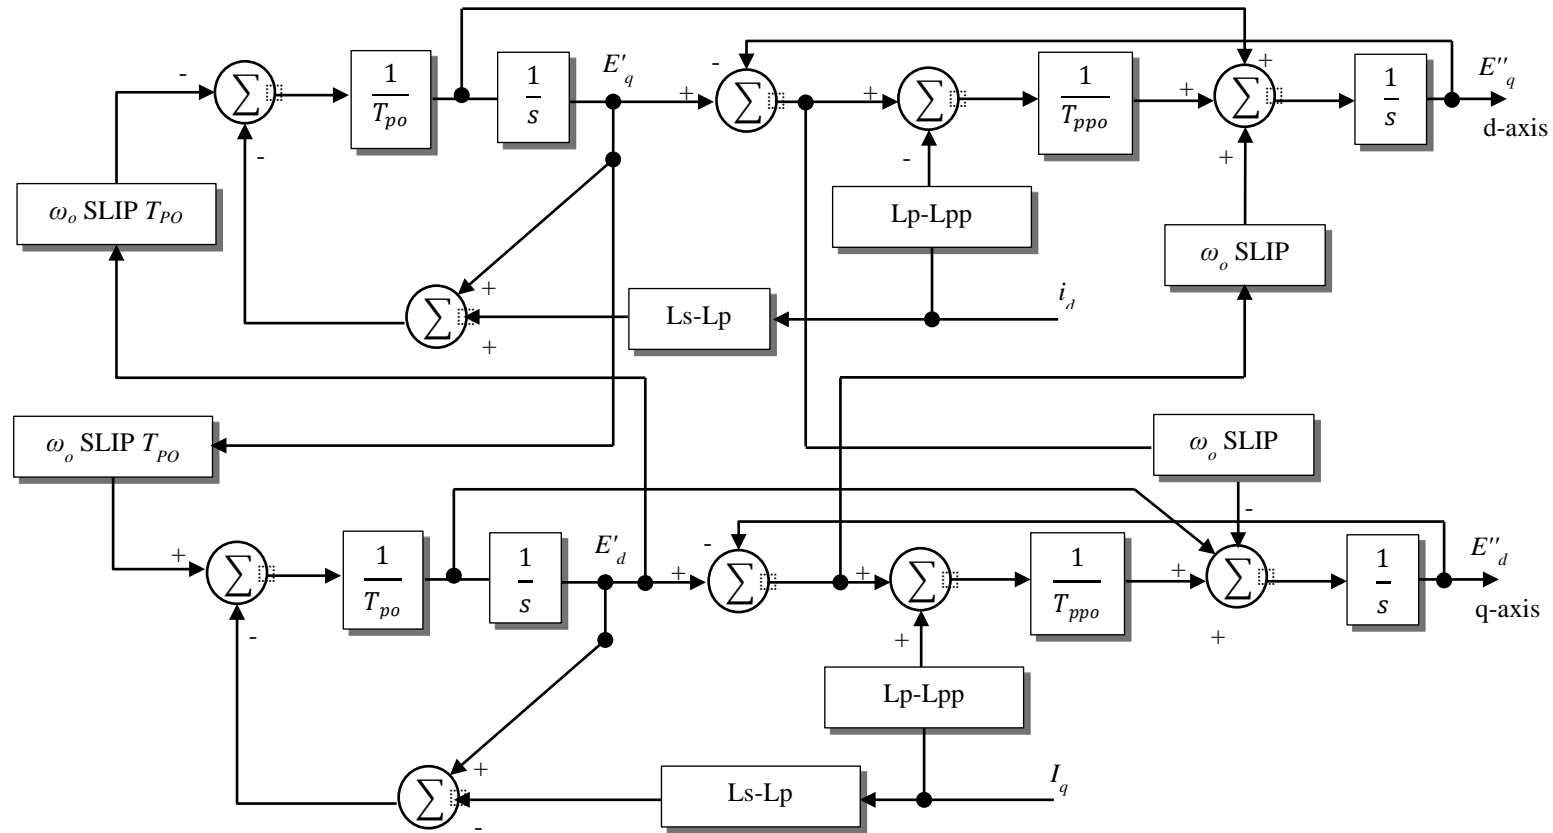

Random Load Model LDRANDOM

The Random Load Model simulates a random load. The user needs to input the Percent of Standard Deviation to generate a random number; a Time for the filter and the Start time when the random load will start to be model. Once the random load model start internally it uses a filter and the generated random number to modify the load.

Model supported by PSLF

Load Characteristic MOTORW

Two-cage or One-cage Induction Machine for Part of a Bus Load Model MOTORW

Model supported by PSLF

Load Characteristic WSCC

Load Characteristic Model WSCC

p1	Constant impedance fraction in p.u.
q1	Constant impedance fraction in p.u.
p2	Constant current fraction in p.u.
q2	Constant current fraction in p.u.
p3	Constant power fraction in p.u.
q3	Constant power fraction in p.u.
p4	Frequency dependent power fraction in p.u.
q4	Frequency dependent power fraction in p.u.
l _{pd}	Real power frequency index in p.u.
l _{qd}	Reactive power frequency index in p.u.

Machine Model GENTPF

*Generator Represented by Uniform Inductance Ratios Rotor
Modeling to Match WSCC Type F Model GENTPF*

$$S_e = 1 + \text{SaturationFunction}(\psi_{ag})$$

Q-Axis Similar except:

$$S_e = 1 + \frac{X_q}{X_d} \text{SaturationFunction}(\psi_{ag})$$

States:

- 1 – Angle
- 2 – Speed w
- 3 – E_q
- 4 – E_{qp}
- 5 – E_d
- 6 – E_{dp}

Model supported by PSLF

Machine Model GENTPJ

Same as the GENTPF model, except that the saturation function input is modeled with an extra term using the K_{is} value as follows.

$$S_e = 1 + \text{SaturationFunction}(\psi_{ag} + K_{is}I_t * \text{sign}(I_d))$$

Q-Axis Similar except:

$$S_e = 1 + \frac{X_q}{X_d} \text{SaturationFunction}(\psi_{ag} + K_{is}I_t * \text{sign}(I_d))$$

Machine Model GENTRA

Machine Model GENTRA *Salient Pole Generator without Amortisseur Windings*

Model supported by PSLF

Machine Model GENWRI

Machine Model GENWRI Wound-rotor Induction Generator Model with Variable External Rotor Resistance

$$R2Tpo = \frac{(L_s - L_l)}{\omega_0 (L_s - L')}$$

$$T_0' = \frac{R2Tpo}{(R2ex + R2)}$$

$$\dot{\phi}_{fd} = -\frac{(\phi_{fd} + S_d + (L_s - L')i_d)}{T_0'} + (slip)\phi_{fq}$$

$$\dot{\phi}_{fq} = -\frac{(\phi_{fq} + S_q + (L_s - L')i_q)}{T_0'} + (slip)\phi_{fd}$$

$$\dot{\phi}_d = \phi_{fd}$$

$$\dot{\phi}_q = \phi_{fq}$$

States:

1 – Epr

2 – Epi

3 – Speed wr

R2Tpo is a constant which is equal to T_0' times the total rotor resistance.

R2 is the internal rotor resistance

R2ex is the internal rotor resistance

$$e_q = \omega_s \phi_d' - L i_d' - R_a i_q'$$

$$e_d = -\omega_s \phi_q' + L i_q' - R_a i_d'$$

$$\phi' = \sqrt{(\phi_d')^2 + (\phi_q')^2}$$

$$S_e = f_{sat}(\phi')$$

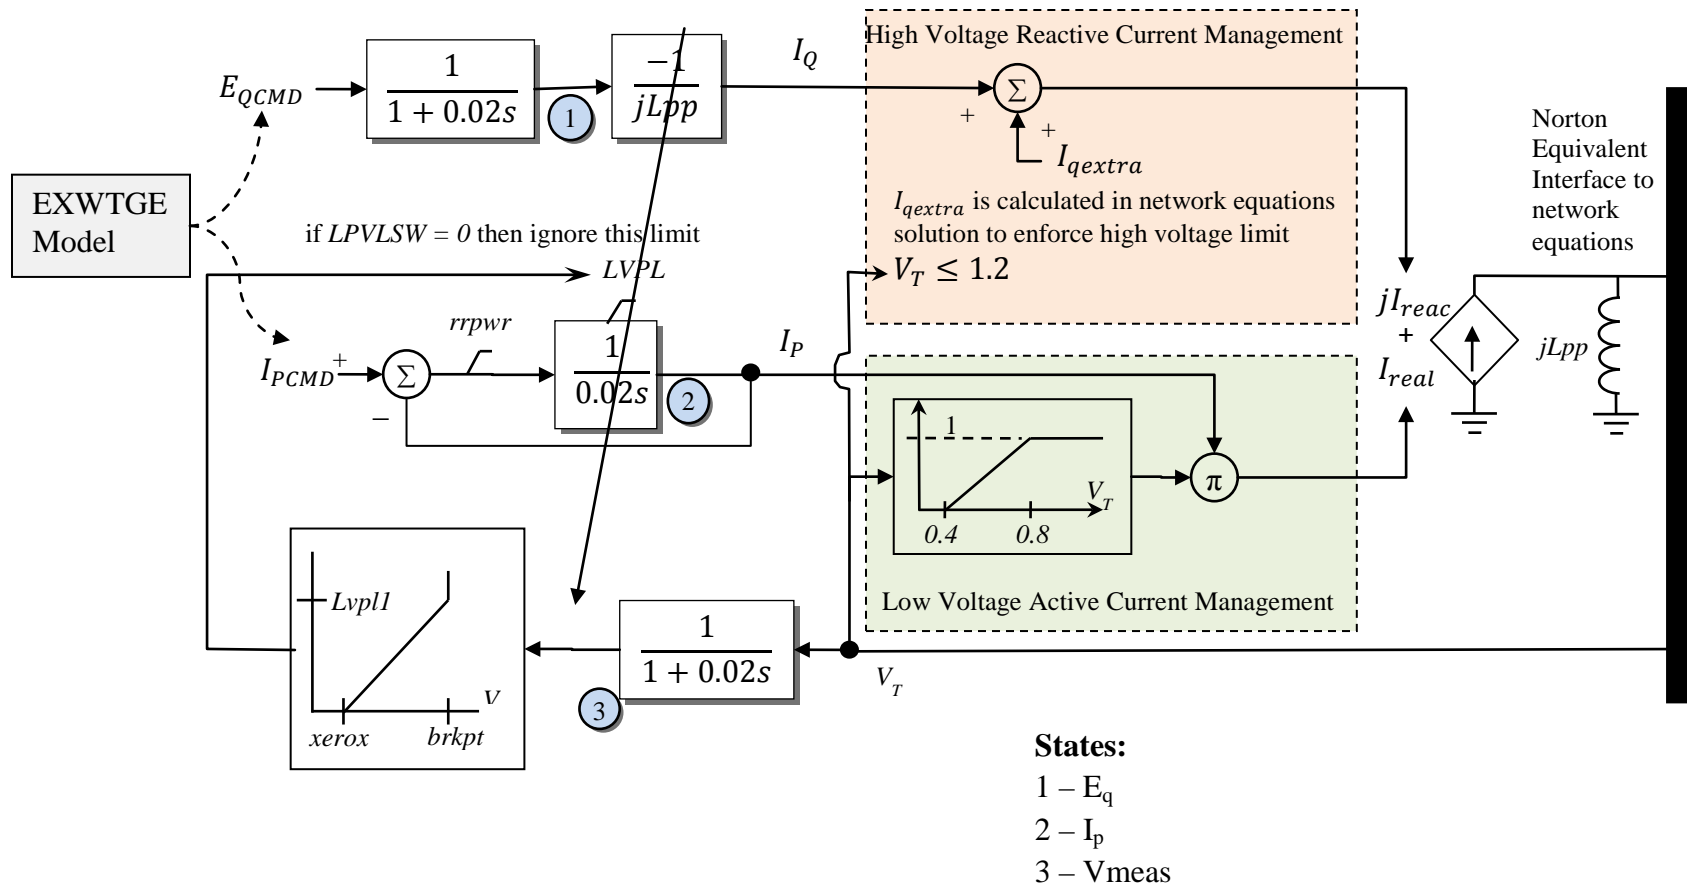

$$S_d = S_e(\phi_d')$$

$$S_q = S_e(\phi_q')$$

Machine Model GEWTG

Machine Model GEWTG Generator/converter model for GE wind turbines – Doubly Fed Asynchronous Generator (DFAG)

When $fcflg = 0$, this means a DFAG machine

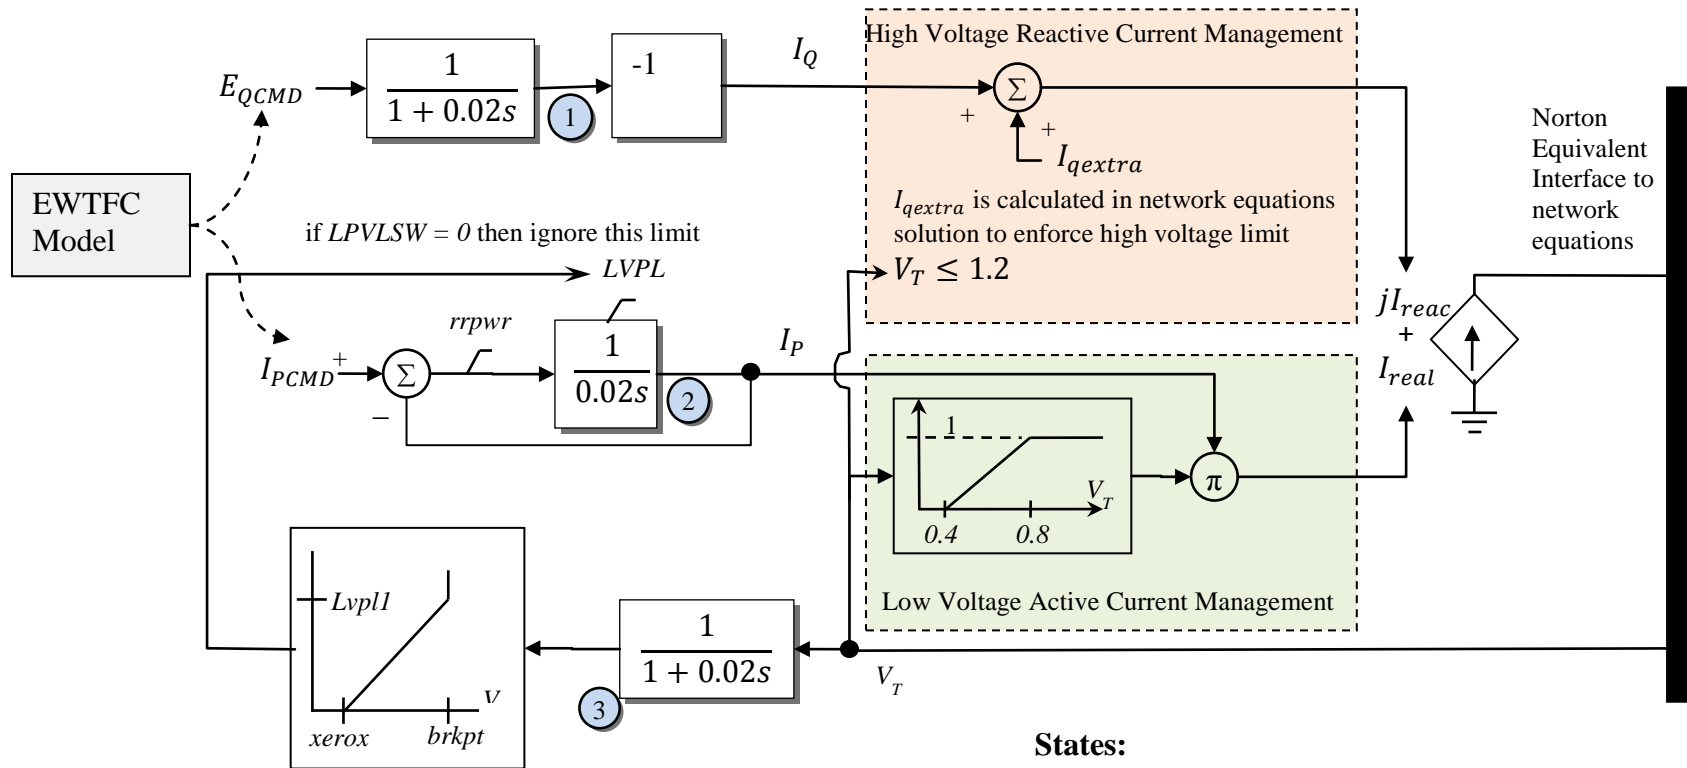

Model supported by PSLF

Machine Model GEWTG

Generator/converter model for GE wind turbines – Full Converter (FC) Models

When $fcflg = 1$, this means a Full Converter machine

States:

- 1 – E_q
- 2 – I_p
- 3 – V_{meas}

Model supported by PSLF

Machine Model InfiniteBusSignalGen

This model extends the functionality of an infinite bus model. Of course in power system dynamics an infinite bus is characterized by a fixed voltage magnitude and frequency. This model makes it easy to change both the voltage magnitude and frequency, hence making it easy to see how other models in the system respond to frequency and voltage disturbances. Presently the model has the ability to do either unit step changes, ramp changes, or constant frequency sinusoidal changes. Up to five separate time segments (changes) can be modeled.

The model dialog is shown as follows. It has two general fields (DoRamp and StartTime,Sec) and then five sets of five fields corresponding to each of the time segments. These fields are described below.

General Options

- **DoRamp** is an integer option that determines whether the non-sinusoidal changes should be discrete (**DoRamp** = 0) or ramping (**DoRamp** = 1). The default is zero.
- **Start Time, Sec** is the number of seconds before the first event occurs. The default is zero.

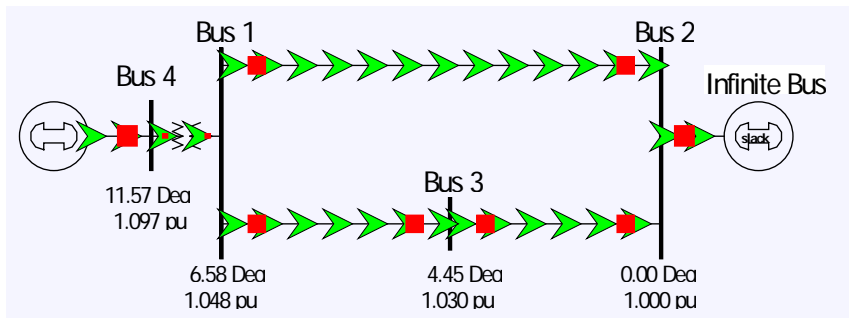

Segment Fields

The next five fields are associated with each time segment.

- **Volt Delta(PU)** : is the per unit magnitude of the voltage change to simulate.
- **Volt Freq(Hz)** : is the frequency of the sinusoidal function to apply to the voltage disturbance. If this value is greater than zero then the voltage disturbance is a sin function with a magnitude of VoltDeltaPU. Set this field to zero when simulating a unit step or ramp disturbance. The default is zero.
- **Speed Delta (Hz)** : is the magnitude of the speed (frequency) change to simulate.
- **Speed Freq(Hz)** : is the frequency of the sinusoidal function to apply to the speed disturbance.
- **Duration (Sec)** : is the duration of the event in seconds. Both the voltage and frequency events have the same duration, with the usual expectation that either one or the other will be applied. If the duration value is negative then this event is ignored. A value of zero indicates the event continues until the end of the simulation (except when a zero is used with a ramp event the ramp is assumed to be a unit step).

These fields are then repeated for the next time segment. Up to five segments can be simulated. The changes are cumulative, so the value assumed at the beginning of the next segment is the value that existed at the end of the previous time segment. The model used is very similar to the PLAYINGEN model.

As an example, consider four bus system shown in upper-left figure on the following page with the generator at bus 2 represented with an **InfiniteBusSignalGen** model. The signal generator is set to run flat for 1 seconds (**Start Time,Sec** = 1), then ramp the voltage up by 0.1 per unit over two seconds, ramp it back down over two seconds, hold flat for one second, then start a 0.1 per unit, 2 Hz oscillation until the end. This input data is shown in bottom-left figure on the next page with the results shown in upper-right. In the results figure the Blue line shows the infinite bus voltage (bus 2), while the red shows the terminal voltage for the other generator (bus 4). The middle-right figure shows a similar test with the generator frequency except the frequency of the change is dropped to 0.5 Hz. Again blue shows the generator 2 value, in this case speed, while red shows the generator 4 speed. When the frequency of the infinite bus speed variation approaches the natural frequency of the bus 4 generator (about 1.8 Hz, calculated through single machine infinite bus analysis), resonance can be seen to occur. This is shown in lower-right figure; note now the input frequency has a magnitude of just 0.1 Hz and the simulation has been extended to twenty seconds.

Rem Bus	Remote Bus
Tfilter	Voltage filter time constant in sec.
tbClose	Circuit breaker closing time for switching shunt ON in sec.
tbOpen	Circuit breaker closing time for switching shunt OFF in sec.
V1On	First voltage threshold for switching shunt capacitor ON in sec.
T1On	First time delay for switching shunt capacitor ON in sec.
V2On	Second voltage threshold for switching shunt capacitor ON in sec.
T2On	Second time delay for switching shunt capacitor ON in sec.
V1Off	First voltage threshold for switching shunt capacitor OFF in sec.
T1Off	First time delay for switching shunt capacitor OFF in sec.
V2Off	Second voltage threshold for switching shunt capacitor OFF in sec.
T2Off	Second time delay for switching shunt capacitor OFF in sec.

Switched Shunt CSSCST

Static Var System Model CSSCST

See CSVGN1, CSVGN3 and CSVGN4 for more information.

Model supported by PSLF

Switched Shunt FACRI_SS

Fast AC Reactive Insertion for Switched Shunts (FACRI_SS)

uv1	Switching Group 1 under voltage level 1 (pu)
uv2	Switching Group 1 under voltage level 2 (pu)
uv1td	Switching Group 1 time delay level 1 (sec)
uv2td	Switching Group 1 time delay level 2 (sec)
inttd	Switching Group 1 first switch time delay, initial time delay (sec)
uv3	Voltage at terminal bus that triggers Switching Group 2 switching logic (pu)
uv4	Switching Group 2 under voltage low level (pu)
uv5	Switching Group 2 under voltage high level (pu)
td1	Switching Group 2 time delay for loop 1 (sec)
td2	Switching Group 2 time delay for loop 2 (sec)
td3	Switching Group 2 time delay for loop 3 (sec)
td4	Switching Group 2 time delay for loop checks (sec)
td5	Duration of time that conditions are checked Monitored Bus b while in each loop (sec)
Extra Object 1	Capacitor 1 – Switching Group 1
Extra Object 2	Capacitor 2 – Switching Group 1
Extra Object 3	Reactor 1 – Switching Group 1
Extra Object 4	Reactor 2 – Switching Group 1
Extra Object 5	Reactor 3 – Switching Group 1
Extra Object 6	Capacitor a1 – Switching Group 1
Extra Object 7	Capacitor a2 – Switching Group 1
Extra Object 8	Reactor a1 – Switching Group 1
Extra Object 9	Monitored Bus b – Switching Group 2
Extra Object 10	Reactor b1 – Switching Group 2
Extra Object 11	Capacitor b1 – Switching Group 2
Extra Object 12	Capacitor b2 – Switching Group 2

Switched Shunt FACRI_SS

Fast AC Reactive Insertion for Switched Shunts (FACRI_SS)

The following pseudo code describes how the inputs are used to determine switched shunt operation:

Switching Group 1 Switching Logic

Each time that voltage and time delay conditions are met for Switching Group 1, the reactors and capacitors are checked in the following order until a device is found that can be switched. Reactors are tripped and capacitors are closed. Only one device is switched each time switching is required.

- (1) Reactor 1
- (2) Reactor a1
- (3) Reactor 2
- (4) Reactor 3
- (5) Capacitor 1
- (6) Capacitor a1
- (7) Capacitor 2
- (8) Capacitor a2

Switching Group 2 Switching Logic

Each time that voltage and time delay conditions are met for Switching Group 2, if the reactor is online it will be tripped first before any capacitor switching. Depending on voltage conditions, capacitors may or may not be turned on. When capacitors are switched, they are checked in the following order until a device is found that can be switched. Only one capacitor is switched each time switching is required.

```
(1) Capacitor b1
(2) Capacitor b2
If (Reactor online) Then Begin
  Trip Reactor
  If (VoltMeasBusb <= uv4) Then Begin
    Do capacitor switching
  End
End
Else If (not Reactor online) Then Begin
  If (VoltMeasBusb <= uv4) or (VoltMeasBusb <= uv5) Then Begin
    Do capacitor switching
  End
End
```

Initialization at the start of transient stability run

FirstSwitchComplete = False

Initialize Switching Group 2 Loop Trackers

Operations performed at each time step

VoltMeas = Voltage at the terminal bus of the switched shunt to which this model is assigned

// If voltage falls below specified thresholds, timers are started to record how long the voltages remain below these thresholds.

// The specific timer pseudo code is not shown here.

If (not FirstSwitchComplete) and ((VoltMeas < uv1 for inttd) or (VoltMeas < uv2 for inttd))

Then Begin

 Check Group 1 Switching

 FirstSwitchComplete = True

End

If (FirstSwitchComplete) Then Begin

 If (VoltMeas < uv1 for uv1td)

 Then Begin

 Check Group 1 Switching

 Reset Group 1 Timer

 End

 If (VoltMeas < uv2 for uv2td)

 Then Begin

 Check Group 1 Switching

 Reset Group 1 Timer

 End

End

If (VoltMeas > uv1) Then Begin

 Reset Group 1 Timers

 FirstSwitchComplete = False

End

Fast AC Reactive Insertion for Switched Shunts (FACRI_SS)

Continued from previous page

// The condition of VoltMeas < uv3 triggers the checking of voltages at Monitored Bus b. This latches on for the duration specified by // td4. The specific timer pseudo code is not shown here, but Group2Timer will be used to keep track of this.

```
VoltMeasBusb = Voltage at Monitored Bus b
If (VoltMeas < uv3) and (Group2Timer < td4) Then Begin
  If (Group2Timer > td1) and (not Group2Loop1Done) Then Begin
    Check Group 2 Switching
    Group2Loop1Done = True
    // Continue doing Check Group 2 Switching for td5 until some switching done
  End
  If (Group2Timer > td2) and (not Group2Loop2Done) Then Begin
    Check Group 2 Switching
    Group2Loop2Done = True
    // Continue doing Check Group 2 Switching for td5 until some switching done
  End
  If (Group2Timer > td3) and (not Group2Loop3Done) Then Begin
    Check Group 2 Switching
    Group2Loop3Done = True
    // Continue doing Check Group 2 Switching for td5 until some switching done
  End
End
Else If (Group2Timer > td4) Then Begin
  Reset Group 2 Timers
  Reset Group 2 Loop Trackers
End
```

Switched Shunt MSC1

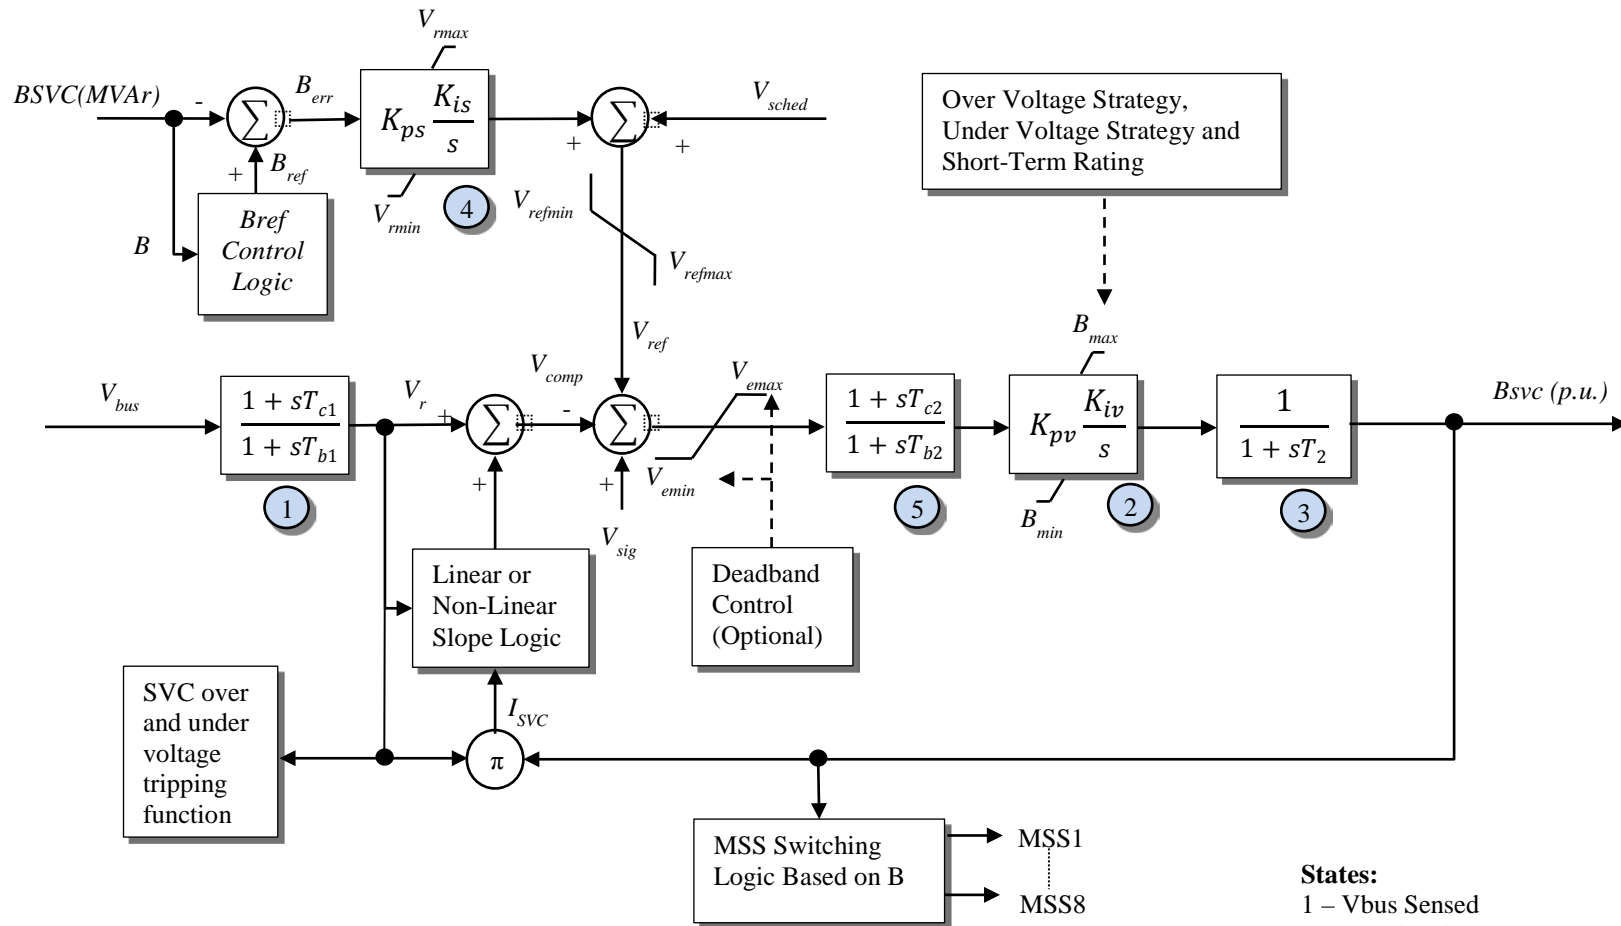

Static Var System Model MSC1

Tin1	Time 1 for Switching in (sec.)
Vmin1	Voltage lower limit 1 (p.u.)
Tout1	Time 1 for Switching out (sec.)
Vmax1	Voltage upper limit 1 (p.u.)
Tin2	Time 1 for Switching in (sec.)
Vmin2	Voltage lower limit 1 (p.u.)
Tout2	Time 1 for Switching out (sec.)
Vmax2	Voltage upper limit 1 (p.u.)
Tlck	Lock out time (sec.)

Model supported by PSLF

Switched Shunt SVSMO1

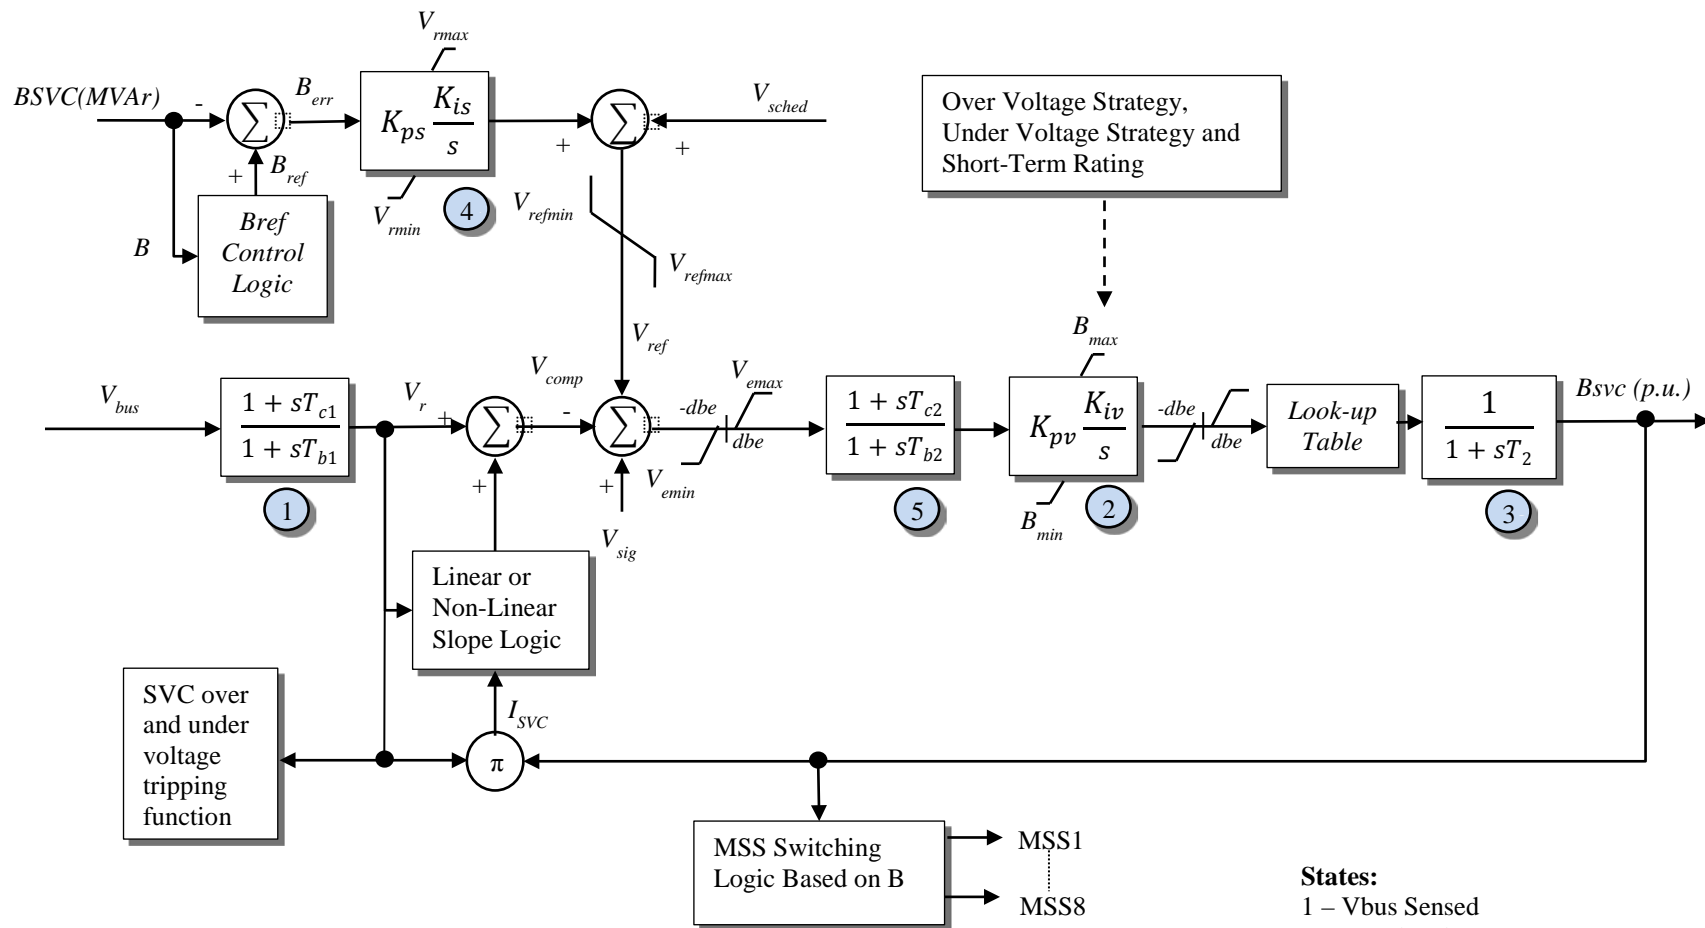

Static Var System Model SVSMO1

Model supported by PSLF

Switched Shunt SVSM02

Static Var System Model SVSM02

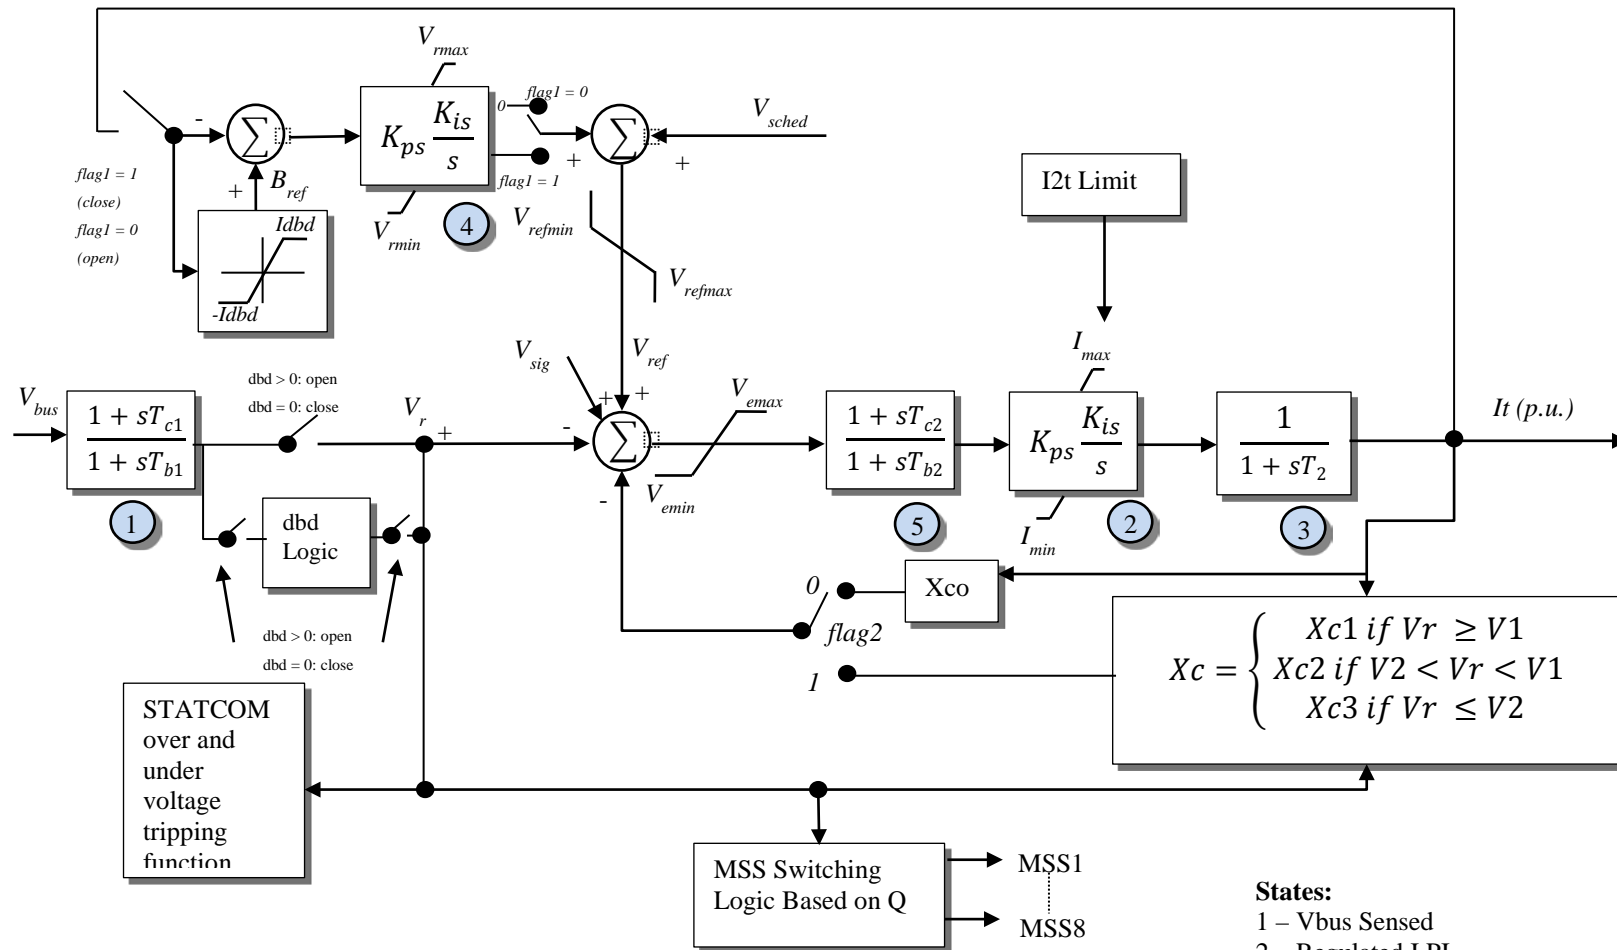

Model supported by PSLF

States:

- 1 – Vbus Sensed
- 2 – Regulated B PI
- 3 – PI Delay
- 4 – Regulated Slow B PI
- 5 – Verr LL

Switched Shunt SVSMO3

Static Var System Model SVSMO3

Model supported by PSLF

Switched Shunt SWSHNT

Switched Shunt SWSHNT

Ib	Remote Bus
NS	Total number of switches allowed
VIN	High voltage limit
PT	Pickup time for high voltage in sec.
ST	Switch time to close if reactor or switch time to open if capacitor in sec.
VIN	Low voltage limit
PT	Pickup time for low voltage in sec.
ST	Switch time to close if reactor or switch time to open if capacitor in sec.

Model supported by PSLF

Model supported by PSSE without T_A, T_B lead/lag block and with $K_{S4} = 1$

Stabilizer PSS3B

Stabilizer PSS3B IEEE (2005) Dual-Input Stabilizer Model

States:

- 1 – Input 1
- 2 – Input 2
- 3 – Washout 1
- 4 – Washout 2
- 5 – Washout 3
- 6 – Filter 1 Internal
- 7 – Filter 1 Output
- 8 – Filter 2 Internal
- 9 – Filter 2 Output

Model supported by PSLF

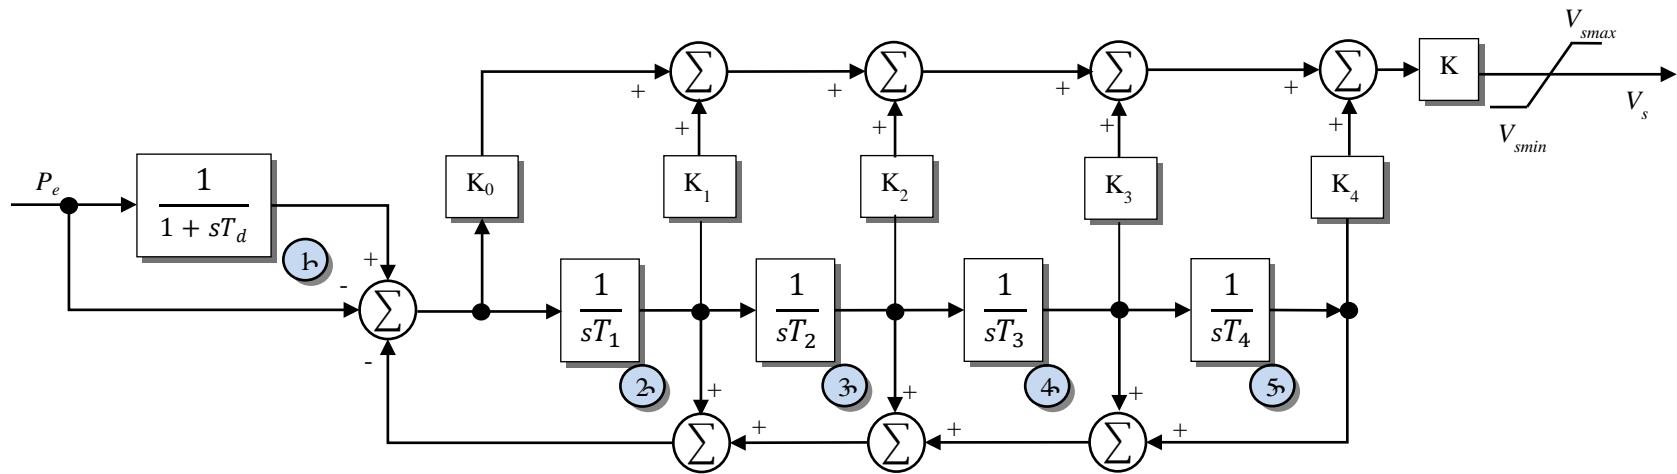

Stabilizer PSSSB

Stabilizer PSSSB IEEE PSS2A Dual-Input Stabilizer Plus Voltage Boost Signal Transient Stabilizer and Vcutoff

Stabilizer PSSSH

Stabilizer PSSSH Model for Siemens "H Infinity" Stabilizer

States:

- 1 – P_e
- 2 – Int1
- 3 – Int2
- 4 – Int3
- 5 – Int4

Model supported by PSLF

Stabilizer PTIST1

Model supported by PSSE but not yet implemented in Simulator

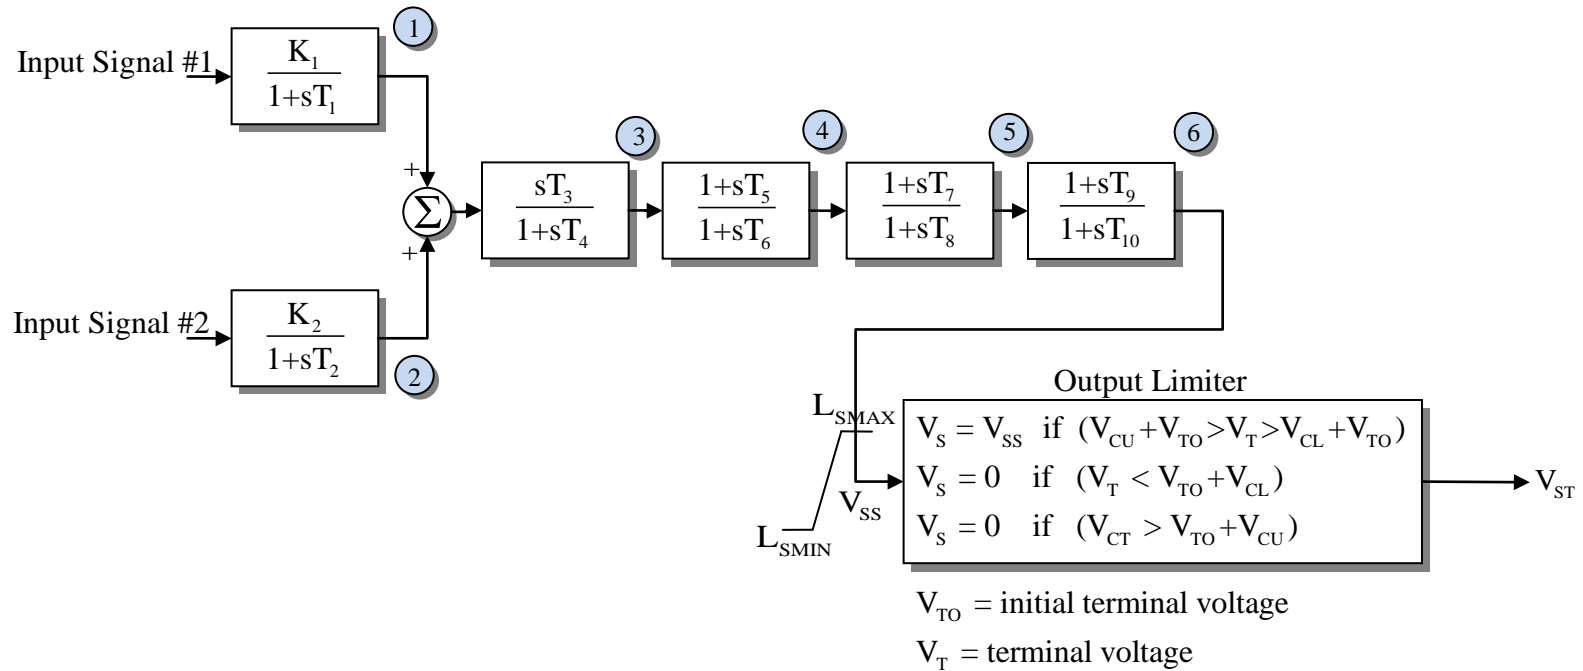

Stabilizer PTIST3

Model supported by PSSE but not yet implemented in Simulator

Stabilizer ST2CUT

Stabilizer ST2CUT *Stabilizing Model with Dual-Input Signals*

States

- 1 - Transducer1
- 2 - Transducer2
- 3 - Washout
- 4 - LL1
- 5 - LL2
- 6 - Unlimited Signal

Model supported by PSSE

Stabilizer STAB1

Stabilizer STAB1 *Speed-Sensitive Stabilizing Model*

States

1 - Washout

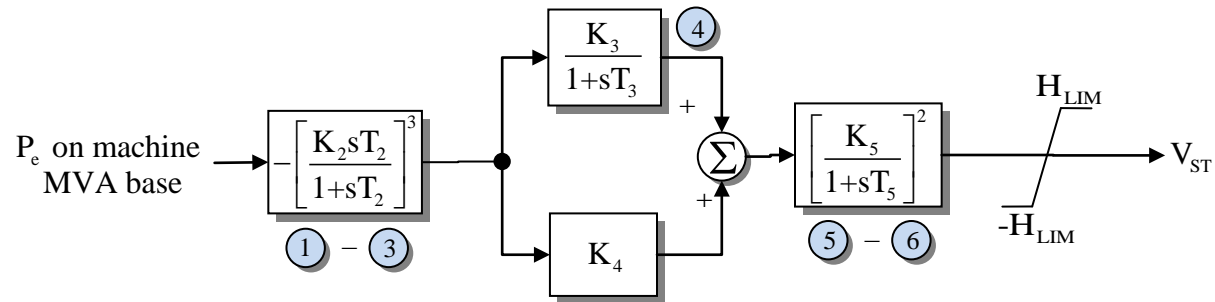

2 - Lead-lag 1

3 - Lead-lag 2

Model supported by PSSE

Stabilizer STAB2A

Stabilizer STAB2A *Power-Sensitive Stabilizing Unit*

States

1 - Input State 1

2 - Input State 2

3 - Input State 3

4 - T_3

5 - Output State 1

6 - Output State 2

Model supported by PSSE

Stabilizer STAB3

States

1 - Int T_t

2 - Int T_{X1}

3 - Unlimited Signal

Model supported by PSSE

Stabilizer STAB4

Stabilizer STAB4 *Power-Sensitive Stabilizer*

States

1 - Input

2 - Reset

3 - LL1

4 - LL2

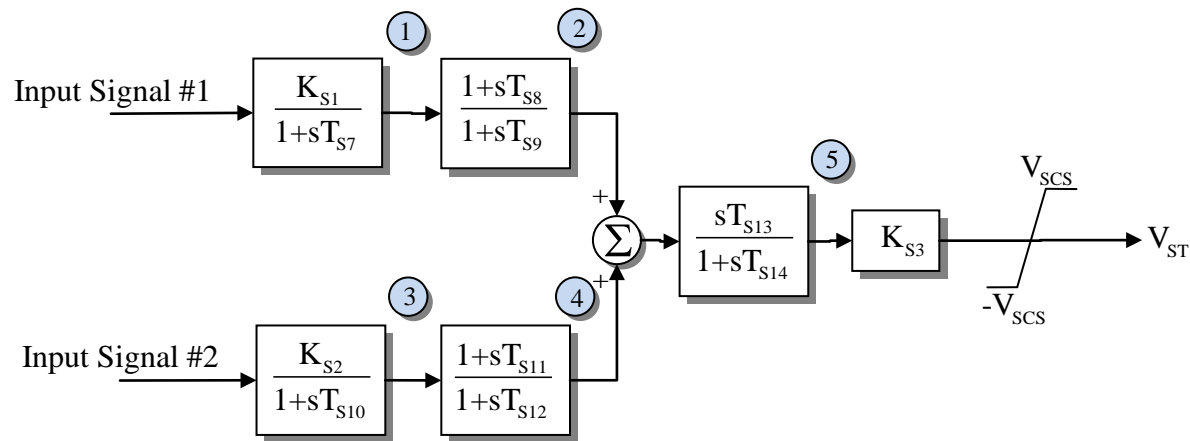

5 - T_d

6 - Unlimited Signal

Model supported by PSSE

Stabilizer STBSVC

Stabilizer STBSVC *WECC Supplementary Signal for Static var Compensator*

States

1 - Transducer1

2 - LL1

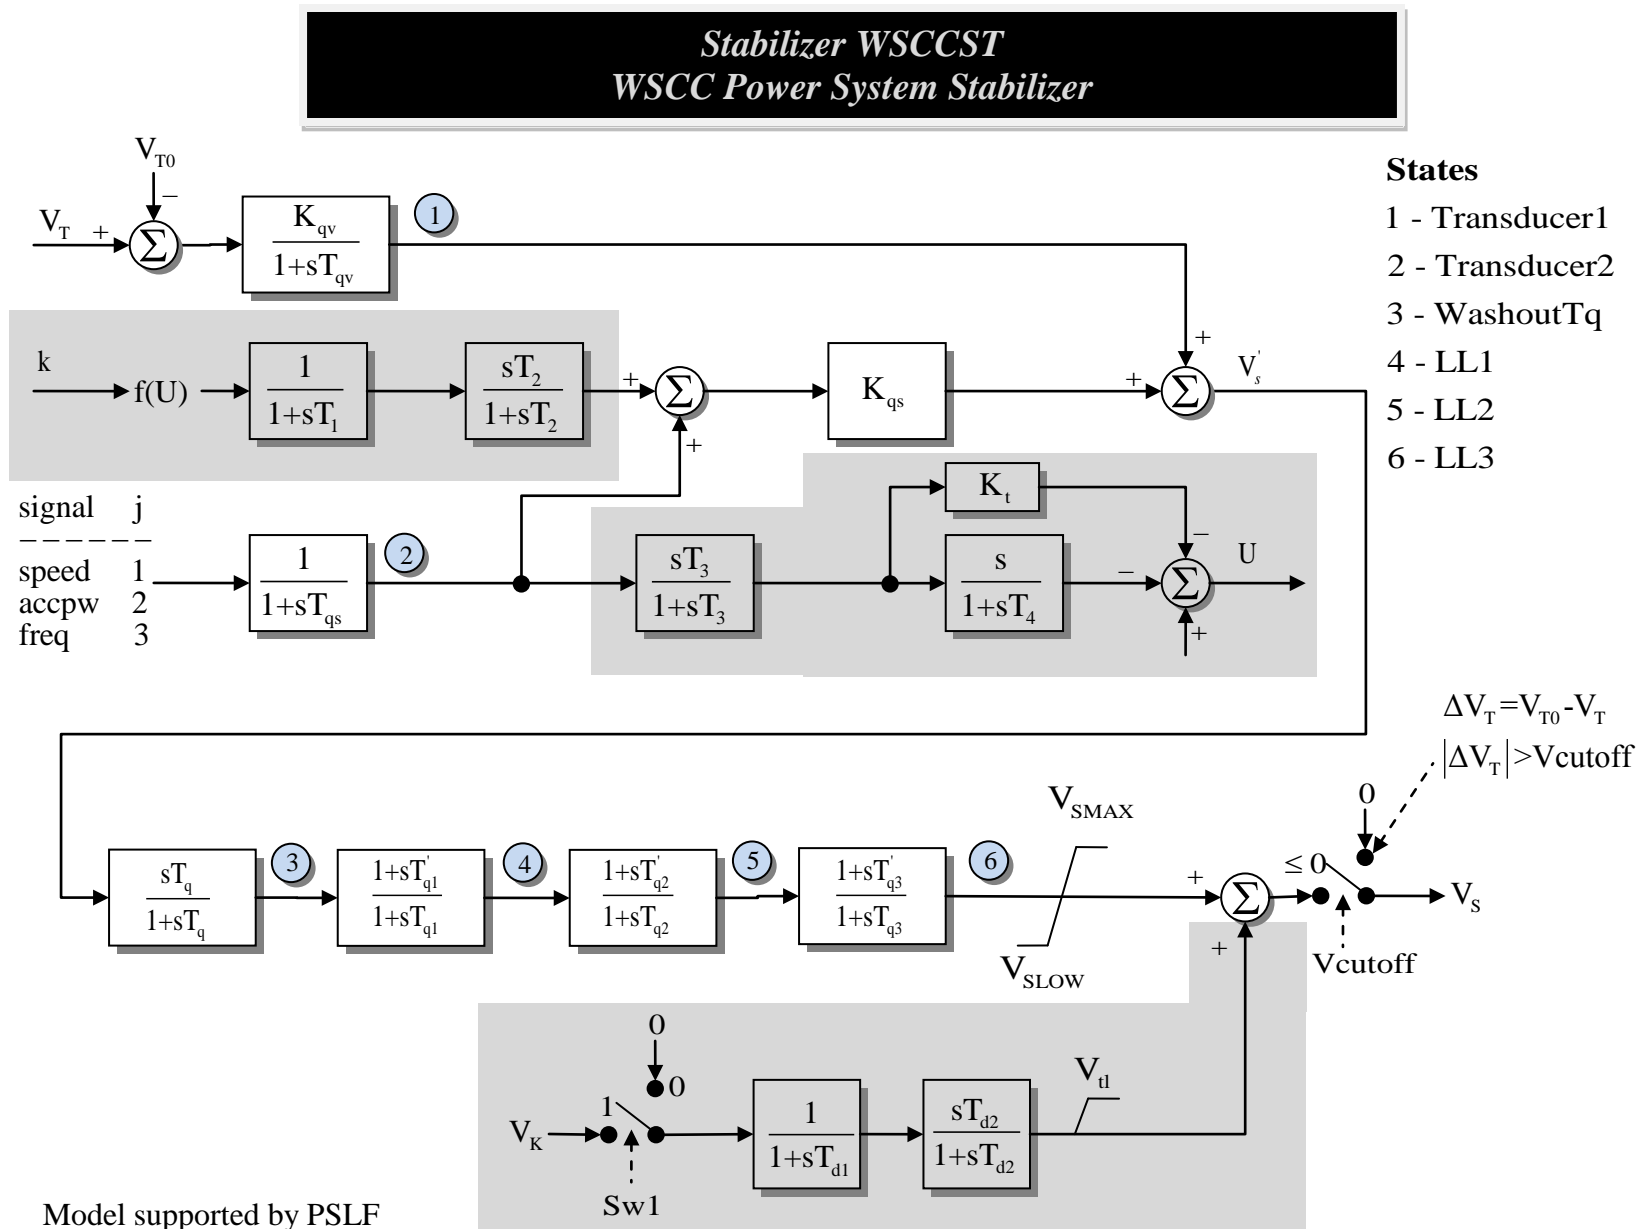

3 - Transducer2

4 - LL2

5 - Washout

Model supported by PSSE

Stabilizer WSCCST

Model supported by PSLF

Blocks in gray have not been implemented in Simulator

Stabilizer WT12A1 and WT1P

Stabilizer WT12A1 and WT1P Pseudo Governor Model for Type 1 and Type 2 Wind Turbines

States

1 - P_{gen}

2 - K_I

3 - T_1

4 - P_{mech}

WT12A1 supported by PSSE with $K_I = \frac{1}{T_1}$

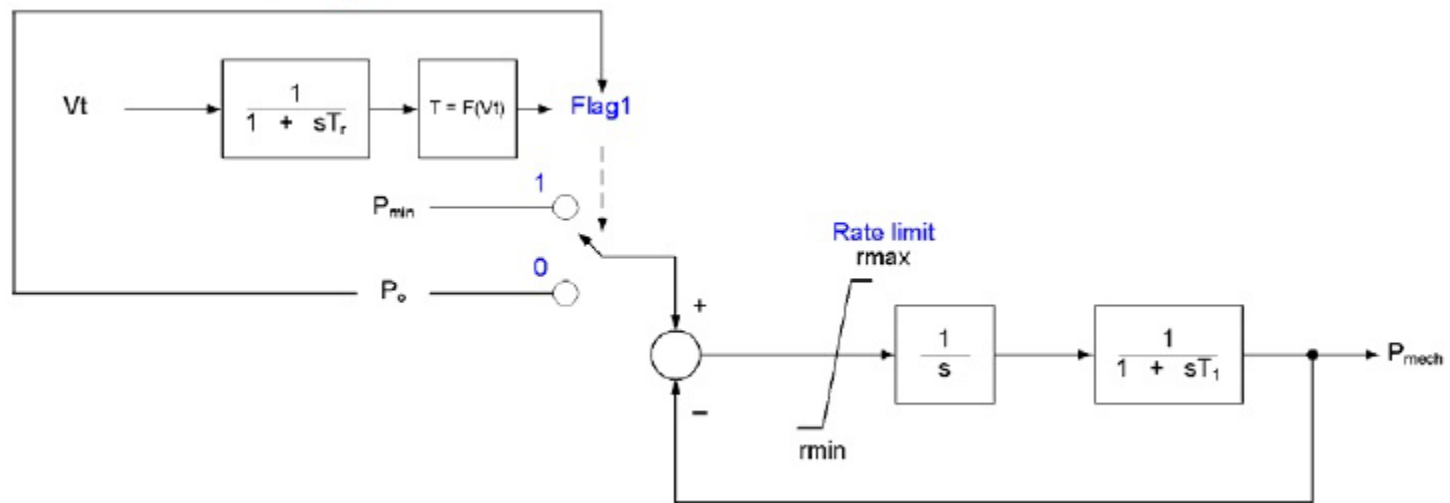

WT1P supported by PSLF

Stabilizer WT1P and WT12A1

WT1P is the same as WT12A1. See WT12A documentation

Stabilizer WT1P_B

Type 1 and 2 Wind Turbine Pitch Controller Model WT1P_B

Model supported by PowerWorld

Stabilizer WT2P

Stabilizer Model WT2P

Model supported by PSLF

Stabilizer WT3P and WT3P1

Stabilizer WT3P and WT3P1 Pitch Control Model for Type 3 Wind Generator

States

- 1 - Pitch
- 2 - PitchControl
- 3 - PitchComp

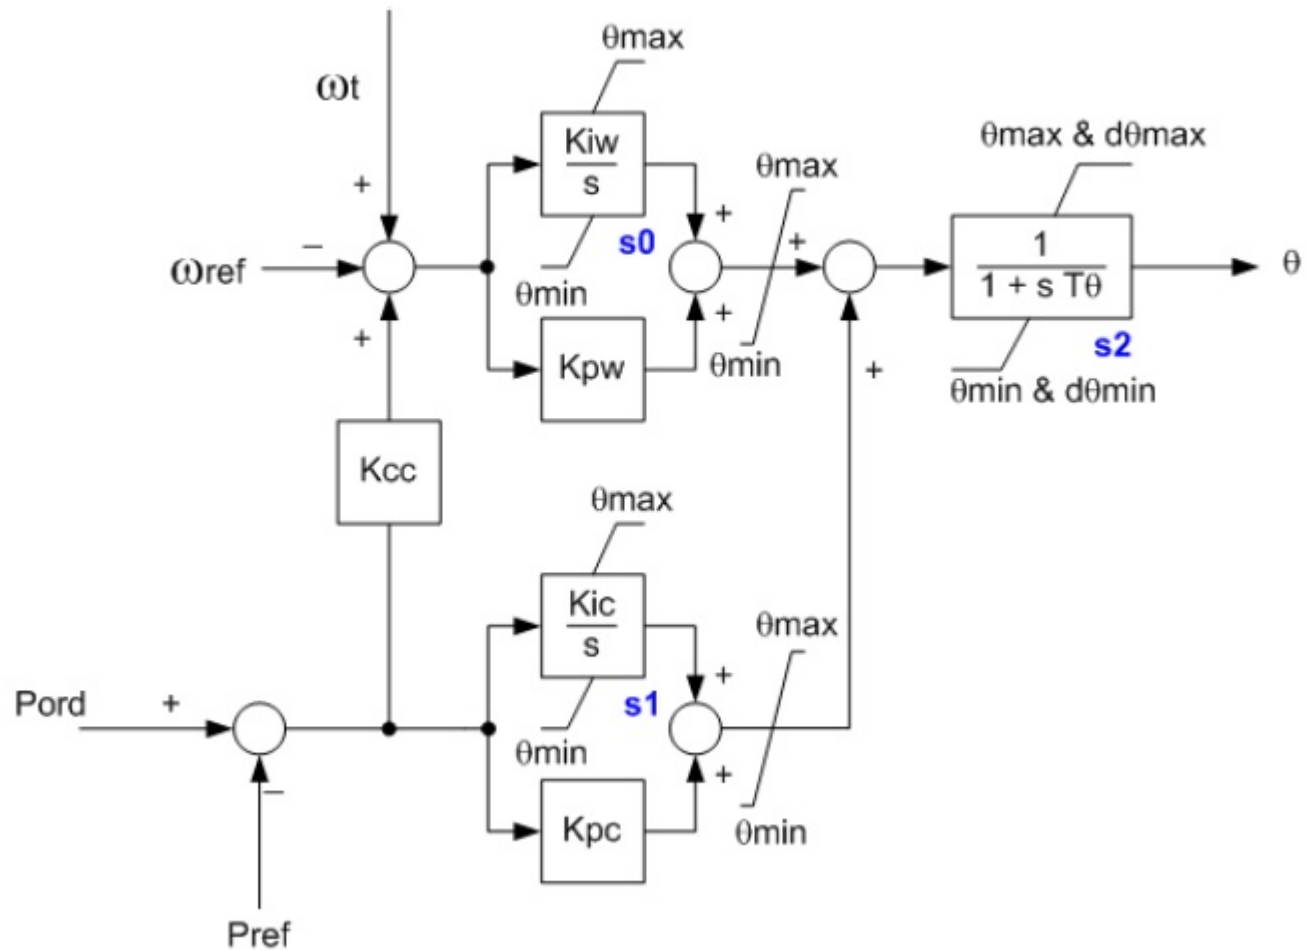

WT3P supported by PSLF

$$T_P = T_{PI}, \Theta_{MAX} = PI_{MAX}, \Theta_{MIN} = PI_{MIN}, \text{ and } R\Theta_{MAX} = PI_{RATE}$$

WT3P1 supported by PSSE with no non-windup limits on pitch control

Stabilizer WTGPT_A

Wind Turbine Generator Pitch-controller Model WTGPT_A

Model supported by PowerWorld
